Logarithm-depth Streaming Multi-label Decision Trees (Supplementary material)

Abstract

This Supplement presents additional details in support of the full article. These include the proofs of the theoretical statements from the main body of the paper and additional theoretical results. We also provide additional algorithm's pseudo-codes. The Supplement also contains the description of the experimental setup, and additional experiments and figures to provide further empirical support for the proposed methodology.

7 ADDITIONAL THEORETICAL RESULTS

Next lemma shows that in isolation, when the purity of the split is perfect, decreasing the value of the objective leads to recovering more balanced splits.

Lemma 6. If a node split is perfectly pure, then

$$\beta \le J - J^*. \tag{6}$$

Next lemma shows that in isolation, when the balancedness of the split is perfect, decreasing the value of the objective leads to recovering more pure splits.

Lemma 7. If a node split is perfectly balanced and assuming that the following condition holds: $\lambda_1(M-1) \ge \lambda_2 \ge \lambda_1 \frac{M-1}{2}$, then $\alpha \le (J+\lambda_2) \frac{2}{M(2\lambda_2 - \lambda_1(M-1))}.$ (7)

Below we provide a new assumption and corresponding theorem that generalizes Theorem 2, by removing the balancedness assumption.

Assumption 7.1. γ -Weak Hypothesis Assumption: for any distribution \mathcal{P} over the data, at each node of the tree \mathcal{T} there exist a partition such that $\sum_{i} \pi_{i} \left| \frac{P_{R}^{i}}{P_{R}} - \frac{P_{L}^{i}}{P_{L}} \right| \geq \gamma$, where $\gamma \in (0, 1]$.

Theorem 3. Under the Weak Hypothesis Assumptions 7.1 and 3.2 for any $\alpha \in [0, 1]$ to obtain $e_r(\mathcal{T}) \leq \alpha$ it suffices to have a tree with t internal nodes that satisfy $(t+1) \geq (\frac{1}{\alpha})^{\frac{16 \ln K}{cr^2\gamma^2(1-b)\log_2(e)}}$, where $b = |P_R + P_L - 1|$.

Below we consider the weak hypothesis assumption that generalizes the Assumption 3.1 to the M-ary case and prove corresponding lemma that generalizes Lemma 5.

Assumption 7.2 (Generalization of Assumption 3.1). γ -Weak Hypothesis Assumption: for any distribution \mathcal{P} over the data, at each node n of the tree \mathcal{T} there exist a partition such that $\sum_{i=1}^{K} \sum_{j=1}^{M} \sum_{l=1}^{M} \pi_i \left| P_j^i - P_l^i \right| \geq \gamma$, where $\gamma \in (0, 1]$.

Lemma 8 (Generalization of Lemma 5). Under the Weak Hypothesis Assumption 7.2, the $e_r(\mathcal{T})$ is monotonically decreasing with every split of the tree.

7.1 Relation of the Objective to Shannon Entropy and Error Bound (Binary Tree Case)

In this section we first show the relation of the objective J to a classical decision-tree criterion, Shannon entropy, and specifically we demonstrate that minimizing the objective leads to the reduction of this criterion. We restrict ourselves to the case of binary tree. We omit the analysis for the M-ary to avoid over-complicating the notation. The entropy of tree leaves in the case when examples can be sent to multiple directions can be calculated as:

$$G = \sum_{\tilde{\mathcal{L}} \subset \mathcal{L}} w_{\tilde{\mathcal{L}}} \sum_{i=1}^{K} \rho_i^{\tilde{\mathcal{L}}} \ln(\frac{1}{\rho_i^{\tilde{\mathcal{L}}}})$$
(8)

where \mathcal{L} is the set of all tree leaves, $\tilde{\mathcal{L}}$ is a subset of the leaves (the summation is taken over all the possible subsets), $\rho_i^{\tilde{\mathcal{L}}}$ is the probability that example with label *i* reaches all the leaves in $\tilde{\mathcal{L}}$, and $w_{\tilde{\mathcal{L}}}$ is the weight of subset of leaves. This weight is defined as the probability that a randomly chosen point from distribution \mathcal{P} reaches all leaves in $\tilde{\mathcal{L}}$. Also note that $\sum_{\tilde{\mathcal{L}} \subset \mathcal{L}} w_{\tilde{\mathcal{L}}} = 1$ and $w_{\tilde{\mathcal{L}}=\varnothing} = 0$.

Theorem 4. Under the Weak Hypothesis Assumptions 3.1 and 3.2, and an additional assumption that each node produces perfectly balanced split, for any $\kappa \in [0, \ln K]$ to obtain $G_t^e \leq \kappa$ it suffices to have a tree with t internal nodes that satisfy

$$(t+1) \ge \left(\frac{G_1}{\kappa}\right)^{\frac{16\ln \kappa}{cr^2\gamma^2(1-b)\log_2(e)}},$$

where $b = |P_R + P_L - 1|$.

8 THEORETICAL PROOFS

Proof of Lemma 1. We rewrite the objective using the total law of probability:

$$J = \left| \sum_{i=1}^{K} \pi_i (P_R^i - P_L^i) \right| - \lambda_1 \sum_{i=1}^{K} \pi_i \left| P_R^i - P_L^i \right| + \lambda_2 \left| \sum_{i=1}^{K} \pi_i (P_R^i + P_L^i) - 1 \right|, \tag{9}$$

where $P_R^i, P_L^i \in [0,1]$ for all i = 1, 2, ..., K. The objective admits optimum on the extremes of the [0,1] interval. Therefore, we define the following:

$$L_1 = \{i : i \in \{1, \dots, K\}, P_R^i = 1 \& P_L^i = 1\}, \ L_2 = \{i : i \in \{1, \dots, K\}, P_R^i = 0 \& P_L^i = 0\},$$
(10)

$$L_3 = \{i : i \in \{1, \dots, K\}, P_R^i = 1 \& P_L^i = 0\}, \ L_4 = \{i : i \in \{1, \dots, K\}, P_R^i = 0 \& P_L^i = 1\}$$
(11)

By substituting the above in the objective we have:

$$J = \left| \sum_{i \in L_3} \pi_i - \sum_{i \in L_4} \pi_i \right| - \lambda_1 \sum_{i \in (L_3 \cup L_4)} \pi_i + \lambda_2 \left| \sum_{i \in (L_3 \cup L_4)} \pi_i + \sum_{i \in L_1} 2\pi_i - 1 \right|.$$
 (12)

We send each example either to the right, left or both directions:

$$\sum_{i \in (L_1 \cup L_3 \cup L_4)} \pi_i = \sum_{i \in L_1} \pi_i + \sum_{i \in L_3} \pi_i + \sum_{i \in L_4} \pi_i = 1.$$
(13)

Thus we can further write

$$J = \left| 1 - \sum_{i \in L_1} \pi_i - 2 \sum_{i \in L_4} \pi_i \right| - \lambda_1 (1 - \sum_{i \in L_1} \pi_i) + \lambda_2 \sum_{i \in L_1} \pi_i.$$
(14)

For ease of notation, we define $a \coloneqq \sum_{i \in L_4} \pi_i$, $a' \coloneqq \sum_{i \in L_3} \pi_i$, and $b \coloneqq \sum_{i \in L_1} \pi_i$. Therefore

$$J = |1 - b - 2a| - \lambda_1(1 - b) + \lambda_2 b = |b + 2a' - 1| - \lambda_1(1 - b) + \lambda_2 b,$$
(15)

where $a, b \in [0, 1]$. Since we are interested in bounding J, we consider the values of a and b at the extremes of [0, 1] interval:

if
$$a = 1$$
 then $b = 0 \rightarrow J = 1 - \lambda_1$, if $b = 1$ then $a = 0 \rightarrow J = \lambda_2$ (16)

if
$$a = 0$$
 then $\begin{cases} b = 0 \ (a' = 1) \rightarrow J = 1 - \lambda_1 \\ b = 1 \rightarrow J = \lambda_2 \end{cases}$ (17)

if
$$b = 0$$
 then
$$\begin{cases} a = 0 \ (a' = 1) \rightarrow J = 1 - \lambda_1 \\ a = 1 \rightarrow J = 1 - \lambda_1 \\ a = 0.5 \rightarrow J = -\lambda_1 \end{cases}$$
 (18)

Therefore $J \in [-\lambda_1, \lambda_2]$.

Next, we show that the perfectly balanced and pure split is attained at the minimum of the objective. The perfectly balanced split is achieved when $P_R = P_L$ and then the balancing term in the objective becomes zero. The perfectly pure split is achieved when the class integrity term in the objective satisfies $\sum_{i=1}^{K} \pi_i |P_R^i - P_L^i| = \sum_{i=1}^{K} \pi_i = 1$. Simultaneously, the following holds $\sum_{i=1}^{K} \pi_i (P_R^i + P_L^i) = 1$, and therefore the multi-way penalty is zero as well. Thus, $J = 0 - \lambda_1 + 0 = -\lambda_1$. In order to prove the opposite direction of the claim, recall that the minimum of the objective occurs for b = 0 and a = 0.5. Since a + a' + b = 1, therefore a' = 0.5. This corresponds to the perfectly pure and balanced split.

Proof of Lemma 2. $P_j^i \in [0, 1]$ for all i = 1, 2, ..., K and j = 1, 2, ..., M. The objective admits optimum on the extremes of the [0, 1] interval. In the following proof we consider a different approach than in the proof of Lemma 1. In order to get the minimum of the objective, we try to minimize each of its terms separately and on the top of that incorporate their correlations. For now, we assume that the first term, the balancing term, is minimized and therefore is equal to zero. We define case C_n as the scenario when for any i = 1, 2, ..., K, $P_j^i = 1$ for n "directions" ($n \le M$), i.e. n distinct js such that $j \in \{1, 2, ..., M\}$, and $P_j^i = 0$ for the remaining j's. The class integrity and multi-way penalty terms can then be derived as follows:

$$J_{\text{class integrity term}|C_n} = \lambda_1 \sum_{i=1}^K \sum_{j=1}^M \sum_{l=j+1}^M \pi_i \left| P_j^i - P_l^i \right| = n(M-n),$$
(19)

$$J_{\text{multi-way penalty term}|C_n} = \lambda_2 \left(\sum_{j=1}^M P_j\right) - 1 = n - 1.$$
(20)

Therefore, the objective value would then become: $J = -\lambda_1 n(M - n) + \lambda_2 (n - 1)$. We aim to have the minimum of the objective for perfectly pure split. The perfectly pure split is achieved when case C_1 holds. Therefore, we need:

$$-\lambda_1(M-1) < -\lambda_1 n(M-n) + \lambda_2(n-1) \text{ for } n \in \{2, \dots, M\}.$$
(21)

The lower-bound of the right side is achieved for n = 2:

$$-\lambda_1(M-1) < -\lambda_1 2(M-2) + \lambda_2 \quad \to \quad M-3 < \frac{\lambda_2}{\lambda_1}.$$
(22)

With the above condition, the minimum of the objective is equal to $-\lambda_1(M-1)$. Note that our first assumption on the balancing term can still hold for all C_n cases. Therefore, we have shown that the minimum of the objective corresponds to the perfectly pure and balanced split.

In order to get the upper-bound for J, we first show that $J_{\text{balancing term}} \leq J_{\text{class integrity term}}$ as follows:

$$J_{\text{balancing term}} = \sum_{j=1}^{M} \sum_{l=j+1}^{M} |P_j - P_l| = \sum_{j=1}^{M} \sum_{l=j+1}^{M} \left| \sum_{i=1}^{K} \pi_i (P_j^i - P_l^i) \right|$$
(23)

$$\leq \sum_{j=1}^{M} \sum_{l=j+1}^{M} \sum_{i=1}^{K} \pi_i \left| P_j^i - P_l^i \right| = J_{\text{class integrity term}}.$$
(24)

Therefore, the maximum of the summation of the terms is achieved when $J_{\text{balancing term}} = J_{\text{class integrity term}}$. The maximum of the multi-way penalty term is attained when sending all examples to every direction, resulting in $J_{\text{multi-way penalty term}} = (M-1)$. In this case, $J_{\text{balancing term}} = J_{\text{class integrity term}} = 0$, and thus, $J = \lambda_2(M-1)$. Hence, we have $J \in [-\lambda_1(M-1), \lambda_2(M-1)]$.

Proof of Lemma 6. The perfectly pure split is attained when $P_j^i = 1$ for only one value of j, and $P_j^i = 0$ for the remaining j's. This leads the class integrity term to satisfy $\sum_{j=1}^{M} \sum_{l=j+1}^{M} \sum_{i=1}^{K} \pi_i |P_j^i - P_l^i| = (M-1)$ and the multi-way penalty term to satisfy $\sum_{i=1}^{k} \pi_i \sum_{j=1}^{M} P_j^i - 1 = 0$. Thus we have:

$$J - J^* = \sum_{j=1}^{M} \sum_{l=j+1}^{M} |P_j - P_l|$$
(25)

$$= \sum_{j=1}^{M} \sum_{l=j+1}^{M} \left| \left(P_{j} - \frac{\sum_{i=1}^{M} P_{i}}{M} \right) - \left(P_{l} - \frac{\sum_{i=1}^{M} P_{i}}{M} \right) \right|.$$
(26)

Let $j^* = \operatorname{argmax}_{j \in \{1,2,\dots,M\}} |P_j - \frac{\sum_{i=1}^M P_i}{M}|$. Without loss of generality assume $P_{j^*} - \frac{\sum_{i=1}^M P_i}{M} \ge 0$ and in that case there exists an l^* such that $P_{l^*} - \frac{\sum_{i=1}^M P_i}{M} \le 0$. Therefore we have:

$$J - J^* \geq \left| \left(P_{j^*} - \frac{\sum_{i=1}^M P_i}{M} \right) - \left(P_{l^*} - \frac{\sum_{i=1}^M P_i}{M} \right) \right|$$

$$(27)$$

$$\geq \left| \left(P_{j^*} - \frac{\sum_{i=1}^M p_i}{M} \right) \right| = \beta.$$
(28)

Proof of Lemma 3. Consider a split with a fixed purity factor α . $J_{\text{purity}}^{\alpha}$ denotes the sum of the class integrity and multi-way penalty terms of the objective function. When subtracting them from the total value of the objective at node n we obtain the balancing term. Thus we have:

$$J - J_{\text{purity}}^{\alpha} = \sum_{j=1}^{M} \sum_{l=j+1}^{M} |P_j - P_l|$$
(29)

$$= \sum_{j=1}^{M} \sum_{l=j+1}^{M} \left| \left(P_{j} - \frac{\sum_{i=1}^{M} P_{i}}{M} \right) - \left(P_{l} - \frac{\sum_{i=1}^{M} P_{i}}{M} \right) \right|.$$
(30)

Let $j^* = \operatorname{argmax}_{j \in \{1,2,\dots,M\}} |P_j - \frac{\sum_{i=1}^M P_i}{M}|$. Without loss of generality assume $P_{j^*} - \frac{\sum_{i=1}^M P_i}{M} \ge 0$ and in that case there exists an l^* such that $P_{l^*} - \frac{\sum_{i=1}^M P_i}{M} \le 0$. Therefore we have:

$$J - J_{\text{purity}}^{\alpha} \geq \left| \left(P_{j^*} - \frac{\sum_{i=1}^{M} P_i}{M} \right) - \left(P_{l^*} - \frac{\sum_{i=1}^{M} P_i}{M} \right) \right|$$
(31)

$$\geq \left| \left(P_{j^*} - \frac{\sum_{i=1}^{M} p_i}{M} \right) \right| = \beta.$$
(32)

Proof of Lemma 7. The perfectly balanced split is attained when $P_1 = P_2 = ... = P_M$. This zeros out the balancing term in the objective function. Hence:

$$J = -\lambda_1 \sum_{i=1}^{K} \sum_{j=1}^{M} \sum_{l=j+1}^{M} \pi_i \left| P_j^i - P_l^i \right| + \lambda_2 \left(\sum_{j=1}^{M} P_j - 1 \right)$$
(33)

$$= -\lambda_1 \sum_{i=1}^{K} \sum_{j=1}^{M} \sum_{l=j+1}^{M} \pi_i \left| P_j^i - P_l^i \right| + \lambda_2 \left(\sum_{i=1}^{K} \sum_{j=1}^{M} \pi_i P_j^i - 1 \right)$$
(34)

$$\geq -\lambda_1 \frac{M-1}{2} \sum_{i=1}^K \sum_{j=1}^M \pi_i P_j^i + \lambda_2 \left(\sum_{i=1}^K \sum_{j=1}^M \pi_i P_j^i - 1 \right).$$
(35)

Thus we have:

$$J + \lambda_2 \ge \left(\lambda_2 - \lambda_1 \frac{M - 1}{2}\right) \sum_{i=1}^K \sum_{j=1}^M \pi_i P_j^i$$
(36)

$$\geq \left(\lambda_2 - \lambda_1 \frac{M-1}{2}\right) \sum_{i=1}^{K} \sum_{j=1}^{M} \pi_i \min(P_j^i, \sum_{l=1}^{M} P_l^i - P_j^i)$$
(37)

$$\geq \left(\lambda_2 - \lambda_1 \frac{M-1}{2}\right) M\alpha. \tag{38}$$

Proof of Lemma 4. Consider a split with a fixed balancedness factor β . $J_{\text{balance}}^{\beta}$ denotes the balancing term of the objective function. When subtracting it from the total value of the objective at node n we will obtain the sum of the class integrity and multi-way penalty terms. Hence:

$$J - J_{\text{balance}}^{\beta} = -\lambda_1 \sum_{i=1}^{K} \sum_{j=1}^{M} \sum_{l=j+1}^{M} \pi_i \left| P_j^i - P_l^i \right| + \lambda_2 \left(\sum_{j=1}^{M} P_j - 1 \right)$$
(39)

$$= -\lambda_1 \sum_{i=1}^{K} \sum_{j=1}^{M} \sum_{l=j+1}^{M} \pi_i \left| P_j^i - P_l^i \right| + \lambda_2 \left(\sum_{i=1}^{K} \sum_{j=1}^{M} \pi_i P_j^i - 1 \right)$$
(40)

$$\geq -\lambda_1 \frac{M-1}{2} \sum_{i=1}^{K} \sum_{j=1}^{M} \pi_i P_j^i + \lambda_2 \left(\sum_{i=1}^{K} \sum_{j=1}^{M} \pi_i P_j^i - 1 \right).$$
(41)

Thus we have:

$$J - J_{\text{balance}}^{\beta} + \lambda_2 \ge \left(\lambda_2 - \lambda_1 \frac{M - 1}{2}\right) \sum_{i=1}^K \sum_{j=1}^M \pi_i P_j^i$$
(42)

$$\geq \left(\lambda_{2} - \lambda_{1} \frac{M-1}{2}\right) \sum_{i=1}^{K} \sum_{j=1}^{M} \pi_{i} \min(P_{j}^{i}, \sum_{l=1}^{M} P_{l}^{i} - P_{j}^{i})$$
(43)

$$\geq \left(\lambda_2 - \lambda_1 \frac{M-1}{2}\right) M\alpha. \tag{44}$$

Proof of Theorem 4. In our algorithm, we recursively find the leaf node with the heaviest weight and decide to partition it to two children. Suppose, after t splits the leaf node n has the highest weight, namely w_n , which will be denoted with w for brevity. This weight is defined as the probability that a randomly chosen data point x drawn from a fixed distribution \mathcal{P} reaches the leaf. Let w_R only and w_L only be the weight of examples reaching only to the right and left child of node n, and w_{both} be the weight of examples reaching to both children. Also let $P_{both} = |P_R + P_L - 1|$. Note that w_R only $= wP_R$ only $= w(P_R - P_{both})$ and w_L only $= wP_L$ only $= w(P_L - P_{both})$. Let ρ be a vector with K elements, which its i^{th} element is ρ_i . Furthermore, let ρ_R , and ρ_L be K-element vectors with $\rho_{i,R}$ and $\rho_{i,L}$ at its i^{th} entry. Note that $\rho_{i,R} = \frac{\rho_i P_R^i}{P_R}$, and $\rho_{i,L} = \frac{\rho_i P_L^i}{P_L}$. Before the node partition the contribution of node n to the total entropy-based objective is $w\tilde{G}(\rho)$. After the split this contribution will be w_R only $\tilde{G}(\rho_R) + w_L$ only $\tilde{G}(\rho_L) + w_{both} \tilde{G}(\rho)$ (Note that for the examples being sent to both directions we average the histograms of the left and right children. Also note that $(w_R \text{ only} + w_R \text{ only} + w_{both}) = 1$) Therefore, we have:

$$\Delta_t := G_t - G_{t+1} = w[\tilde{G}(\boldsymbol{\rho}) - P_R \text{ only } \tilde{G}(\boldsymbol{\rho}_R) - P_L \text{ only } \tilde{G}(\boldsymbol{\rho}_L) - P_{\text{both}} \tilde{G}(\boldsymbol{\rho})]$$

$$\tag{45}$$

$$= w[\tilde{G}(\boldsymbol{\rho}) - (P_R - P_{both})\tilde{G}(\boldsymbol{\rho}_R) - (P_L - P_{both})\tilde{G}(\boldsymbol{\rho}_L) - P_{both}\tilde{G}(\boldsymbol{\rho})].$$
(46)

Recall that the Shannon entropy is strongly concave with respect to l_1 -norm (see Shalev-Shwartz, 2012, Example 2.5), and $\boldsymbol{\rho} = (P_R - \frac{1}{2}P_{both})\boldsymbol{\rho}_R + (P_L - \frac{1}{2}P_{both})\boldsymbol{\rho}_L$, where $P_{both} = P_R + P_L - 1$. Without loss of generality assume $P_R = P_L + \eta$. Hence we re-write Δ_t as follows:

$$\Delta_t = w[(1 - P_{both})\tilde{G}(\boldsymbol{\rho}) - (\frac{1 + \eta - P_{both}}{2})\tilde{G}(\boldsymbol{\rho}_R) - (\frac{1 - \eta - P_{both}}{2})\tilde{G}(\boldsymbol{\rho}_L)]$$
(47)

$$= w(1 - P_{both})[\tilde{G}(\boldsymbol{\rho}) - (\frac{1 + \eta - P_{both}}{2(1 - P_{both})})\tilde{G}(\boldsymbol{\rho}_R) - (\frac{1 - \eta - P_{both}}{2(1 - P_{both})})\tilde{G}(\boldsymbol{\rho}_L)].$$
(48)

(49)

We can then use the result from Theorem 2.1.9 in Nestrov (2004):

$$\Delta_t \ge w(1 - P_{both}) \left[\frac{1}{8} ||\boldsymbol{\rho}_R - \boldsymbol{\rho}_L||_1^2 \right]$$
(50)

$$= w(1 - P_{both})r^2 \left[\frac{1}{8}||\boldsymbol{\pi}_R - \boldsymbol{\pi}_L||_1^2\right]$$
(51)

$$= w(1 - P_{both})r^{2} \left[\frac{1}{8} \left(\sum_{i=1}^{K} \left| \frac{\pi_{i}P_{R}^{i}}{P_{R}} - \frac{\rho_{i}P_{L}^{i}}{P_{L}} \right| \right)^{2} \right].$$
(52)

Here we use the assumption that we have a balance split, i.e. $P_R = P_L$, therefore we continue as follows:

$$= w(1 - P_{both}) \frac{r^2}{8P_R^2} \left(\sum_{i=1}^K \pi_i |P_R^i - P_L^i| \right)^2$$
(53)

$$\geq w(1 - P_{both}) \frac{r^2}{8} \left(\sum_{i=1}^{K} \pi_i |P_R^i - P_L^i| \right)^2.$$
(54)

Now by applying the WHA 3.2:

$$\Delta_t \ge w(1-b)\frac{r^2}{8}\gamma^2.$$
(55)

Note that by WHA 3.2 $b \in [0, 1)$. Also note that $w \ge \frac{G_t c}{(t+1) \ln K}$. This comes from the fact that at each step we choose the leaf node with maximum weight. Hence with WHA2, $w = \max_{l \in \mathcal{L}} w_l \ge \frac{c}{(t+1)}$. Also note that uniform distribution maximizes the entropy, i.e. $G_t \le \ln K$. Accordingly we have:

$$\Delta_t \ge \frac{G_t c}{(t+1)\ln K} [\frac{r^2}{8} \gamma^2 (1-b)].$$
(56)

By letting $\eta = \frac{1}{2} \sqrt{\frac{cr^2 \gamma^2 (1-b)}{2 \ln K}}$, we have $\Delta_t \ge \frac{\eta^2 G_t}{(t+1)}$. Thus, we have the following recursion inequality:

$$G_{t+1} \le G_t - \Delta_t \le G_t - \frac{\eta^2 G_t}{(t+1)} = G_t [1 - \frac{\eta^2}{(t+1)}].$$
(57)

Then by applying the same proof technique as in Kearns and Mansour (1999) we get the following relationship:

$$G_{t+1} \le G_1 e^{-\eta^2 \log_2(t+1)/2}.$$
(58)

Therefore, to reduce $G_{t+1} \leq \kappa$ it suffices to have (t+1) splits such that $\log_2(t+1) \geq \ln(\frac{G_1}{\kappa})^{\frac{2}{\eta^2}}$. Substituting $\log_2(t+1) = \ln(t+1)\log_2(e)$ results in:

$$\ln(t+1) \ge \ln(\frac{G_1}{\kappa})^{\frac{2}{\eta^2 \log_2(e)}} \Leftrightarrow (t+1) \ge (\frac{G_1}{\kappa})^{\frac{2}{\eta^2 \log_2(e)}}.$$
(59)

We next proceed to the proof of Theorem 2.

Proof of Theorem 2. This proof follows the proof of the Theorem 4. Below we directly calculate the error bound. Recall $w_{\tilde{\mathcal{L}}}$ to be the probability that a data point x reached the subset of leaves $\tilde{\mathcal{L}}$. Recall that $\rho_i^{\tilde{\mathcal{L}}}$ is the probability that the data point x has label i given that x reached $\tilde{\mathcal{L}}$, i.e. $\rho_i^{\tilde{\mathcal{L}}} = P(i \in t(x) | x \text{ reached } \tilde{\mathcal{L}})$. Note that each example has r labels, and let's assume we assign first majority r labels from the $\rho_i^{\tilde{\mathcal{L}}}$ histogram to any example reaching $\tilde{\mathcal{L}}$, i.e. $y_r(x) = \{j_1, j_2, ..., j_r\}$,

where $j_1 = \operatorname{argmax}_{k \in \{1,2,\dots,K\}}(\rho_k^{\tilde{\mathcal{L}}}), j_2 = \operatorname{argmax}_{k \in \{1,2,\dots,K\} \setminus j_1}(\rho_k^{\tilde{\mathcal{L}}}), \dots, j_r = \operatorname{argmax}_{k \in \{1,2,\dots,K\} \setminus \{j_1,\dots,j_{r-1}\}}(\rho_k^{\tilde{\mathcal{L}}})$. We then expand the *r*-level multi-label error as follows:

$$\epsilon_r(\mathcal{T}) = \frac{1}{r} \sum_{i=1}^K P(i \in y_r(x), i \notin t(x))$$
(60)

$$= \frac{1}{r} \sum_{i=1}^{K} P(i \in t(x), i \notin y_r(x))$$
(61)

$$= \frac{1}{r} \sum_{\tilde{\mathcal{L}} \in \mathcal{L}} w_{\tilde{\mathcal{L}}} \sum_{i=1}^{K} P(i \in t(x), i \notin y_r(x) | x \text{ reached } \tilde{\mathcal{L}})$$
(62)

$$= \frac{1}{r} \sum_{\tilde{\mathcal{L}} \in \mathcal{L}} w_{\tilde{\mathcal{L}}} \sum_{\substack{i=1\\i \neq j_1, \dots, j_R}}^K P(i \in t(x) | x \text{ reached } \tilde{\mathcal{L}})$$
(63)

$$= \frac{1}{r} \sum_{\tilde{\mathcal{L}} \in \mathcal{L}} w_{\tilde{\mathcal{L}}} \left(\sum_{i=1}^{K} \rho_{i}^{\tilde{\mathcal{L}}} - \max_{k \in \{1,2,\dots,K\}} \rho_{k}^{\tilde{\mathcal{L}}} - \max_{k \in \{1,2,\dots,K\} \setminus j_{1}} \rho_{k}^{\tilde{\mathcal{L}}} - \max_{k \in \{1,2,\dots,K\} \setminus \{j_{1},j_{2}\}} \rho_{k}^{\tilde{\mathcal{L}}} - \cdots - \max_{k \in \{1,2,\dots,K\} \setminus \{j_{1},j_{2},\dots,j_{r-1}\}} \rho_{k}^{\tilde{\mathcal{L}}} \right),$$
(64)

where $w_{\tilde{\mathcal{L}}}$ denote the probability that example x reaches $\tilde{\mathcal{L}}$ and \mathcal{L} denote the set of all leaves of the tree.

Next we will find the Shannon entropy bound with respect to the error and show that the entropy of the tree, denoted as $G(\mathcal{T})$, upper-bounds the error. Note that:

$$G(\mathcal{T}) = \sum_{\tilde{\mathcal{L}} \in \mathcal{L}} w_{\tilde{\mathcal{L}}} \sum_{i=1}^{K} \rho_i^{\tilde{\mathcal{L}}} \ln\left(\frac{1}{\rho_i^{\tilde{\mathcal{L}}}}\right) \geq \sum_{l \in \mathcal{L}} w_{\tilde{\mathcal{L}}} \sum_{\substack{i=1\\i \neq j_1, \dots, j_r}}^{K} \rho_i^{\tilde{\mathcal{L}}} \ln\left(\frac{1}{\rho_i^{\tilde{\mathcal{L}}}}\right).$$
(65)

Note that $\sum_{i=1}^{K} \rho_i^{\tilde{\mathcal{L}}} = r$. Thus for any i = 1, 2, ..., K such that $i \neq j_1, ..., j_r$ it must hold that $\rho_i^{\tilde{\mathcal{L}}} \leq \frac{1}{2}$. We continue as follows

$$G(\mathcal{T}) \geq \sum_{\tilde{\mathcal{L}} \in \mathcal{L}} w_{\tilde{\mathcal{L}}} \sum_{\substack{i=1 \ i \neq j_1, \dots, j_r}}^K \rho_i^{\tilde{\mathcal{L}}} \ln(2)$$

$$\geq \ln(2) \sum_{\tilde{\mathcal{L}} \in \mathcal{L}} w_{\tilde{\mathcal{L}}} \left(\sum_{i=1}^K \rho_i^{\tilde{\mathcal{L}}} - \max_{k \in \{1, 2, \dots, K\}} \rho_k^{\tilde{\mathcal{L}}} - \max_{k \in \{1, 2, \dots, K\} \setminus \{j_1, j_2\}} \rho_k^{\tilde{\mathcal{L}}} - \max_{k \in \{1, 2, \dots, K\} \setminus \{j_1, j_2, \dots, j_{r-1}\}} \rho_k^{\tilde{\mathcal{L}}} \right)$$

$$= \ln(2) r \epsilon_r(\mathcal{T}) \geq \epsilon_r(\mathcal{T}),$$
(66)
(66)
(66)

where the last inequality comes from the fact that $r \ge 1/\ln(2)$. Now recall that $G_1 \le \ln K$ and normalizing κ in Theorem 4 finishes the proof.

Proof of Theorem 3. The proof follows the same steps as Theorem 4 until Equation 52. Applying WHA 7.1 at this point will result in the same result as in Equation 55. The rest of the proof would be the same as Theorems 4 and 2. \Box

Proof of Theorem 1. Since we assume the objective is minimized in every node of the tree, therefore each node is sending examples to only one of its children and consequently each example descends to only one leaf. Thus in any leaf l, we store label histograms and assign first r labels from the histogram to any example reaching that leaf, i.e. $y(x) = \{j_1, j_2, ..., j_r\}$, where $j_1 = \operatorname{argmax}_{k \in \{1,2,...,K\}} \rho_k^l$, $j_2 = \operatorname{argmax}_{k \in \{1,2,...,K\} \setminus j_1} (\rho_k^l)$,..., $j_r = \operatorname{argmax}_{k \in \{1,2,...,K\} \setminus \{j_1,...,j_{r-1}\}} (\rho_k^l)$ and ρ_i^l is the probability that the data point x has label i given that x has reached leaf l, i.e. $\rho_i^l = P(i \in t(x) | x \text{ reached } l)$.

We next expand the *r*-level multi-label error as follows:

$$\epsilon_r(\mathcal{T}) = \frac{1}{r} \sum_{i=1}^K P(i \in y_r(x), i \notin t(x))$$
(68)

$$= \frac{1}{r} \sum_{i=1}^{K} P(i \in t(x), i \notin y_r(x))$$
(69)

$$= \frac{1}{r} \sum_{l \in \mathcal{L}} w(l) \sum_{i=1}^{K} P(i \in t(x), i \notin y_r(x) | x \text{ reached } l)$$
(70)

$$= \frac{1}{r} \sum_{l \in \mathcal{L}} w(l) \sum_{\substack{i=1\\i \neq j_1, \dots, j_r}}^{K} P(i \in t(x) | x \text{ reached } l)$$
(71)

$$= \frac{1}{r} \sum_{l \in \mathcal{L}} w(l) \left(\sum_{i=1}^{K} \rho_i^{(l)} - \max_{k \in \{1, 2, \dots, K\}} \rho_k^l - \max_{k \in \{1, 2, \dots, K\} \setminus j_1} \rho_k^l \right)$$
(72)

$$-\max_{k\in\{1,2,\ldots,K\}\setminus\{j_1,j_2\}}\rho_k^l-\cdots-\max_{k\in\{1,2,\ldots,K\}\setminus\{j_1,j_2,\ldots,j_{r-1}\}}\rho_k^l\right),$$

where w(l) denote the probability that example x reaches leaf l and \mathcal{L} denote the set of all leaves of the tree.

From Lemma 1 (for binary tree) and Lemma 2 (for M-ary tree) it follows that for any node in the tree, the corresponding split is balanced and the following holds: $|P_j^i - P_{j'}^i| = 1$ for all labels i = 1, 2, ..., K and all pairs of children nodes (j, j') of the considered node such that $j, j' \in \{1, 2, ..., M\}$ and $j \neq j'$. Thus when splitting any node, its label histogram is divided in such a way that its children have non-overlapping label histograms, i.e. $\forall_{i=1,2,...,K} \forall_{j,j' \in \{1,2,...,M\}, j \neq j'} \rho_i^{(j)} \rho_i^{(j')} = 0$, where $\rho_i^{(j)}$ and $\rho_i^{(j')}$ denote the i^{th} entry in the normalized label histograms of children nodes j and j' respectively. After $\log_M(K/r)$ splits we obtain leaves with non-overlapping histograms, i.e. for any two leaves l_1 and l_2 such that $l_1, l_2 \in \mathcal{L}$ and $l_1 \neq l_2, \forall_{i=1,2,...,K} \rho_i^{(l_1)} \cdot \rho_i^{(l_2)} = 0$. In each leaf the label histogram contains r non-zero entries. Based on the above it follows that $G(\mathcal{T}) = 0$. Consequently, using Equation 67 we obtain that the multi-label error $\epsilon_r(\mathcal{T})$ is equal to zero as well. This directly implies that $\epsilon_{\hat{r}}(\mathcal{T}) = 0$ for any $\hat{r} = 1, 2, ..., r$.

Proof of Lemma 8 (Proof of Lemma 5 follows directly as Lemma 5 is a special case of Lemma 8). In our algorithm we store label histograms for each node, and at testing we assign to an example top r labels obtained from averaging the histograms of the leaves to which this example has descended to. At training, we recursively find the node with the highest priority and partition it to two children. Here we are examining the change of error with one node split. We consider examples reaching that node and without loss of generality we assume they have reached only this node. For each such example x we assign the top r labels from the histogram of the analyzed node, i.e. $y_r(x) = \{k_1, k_2, ..., k_r\}$, where $k_1 = \operatorname{argmax}_{k \in \{1,2,...,K\}} \rho_k$, $k_2 = \operatorname{argmax}_{k \in \{1,2,...,K\} \setminus j_1}(\rho_k)$,..., $k_r = \operatorname{argmax}_{k \in \{1,2,...,K\}} (\rho_k)$ and ρ_i is the probability that the data point x has label i given that x has reached node n, i.e. $\rho_i = P(i \in t(x) | x \text{ reached } n)$. After t splits the Precision can be expanded as follows:

$$(P@r)^{t} = \frac{1}{r} \sum_{i=1}^{K} P(i \in t(x), i \in y_{r}(x))$$
(73)

$$= \frac{1}{r} \Big(\max_{k \in \{1,2,\dots,K\}} \rho_k + \max_{k \in \{1,2,\dots,K\} \setminus j_1} \rho_k + \dots + \max_{k \in \{1,2,\dots,K\} \setminus \{j_1,j_2,\dots,j_{r-1}\}} \rho_k \Big)$$
(74)

$$= \max_{k \in \{1,2,\dots,K\}} \pi_k + \max_{k \in \{1,2,\dots,K\} \setminus j_1} \pi_k + \dots + \max_{k \in \{1,2,\dots,K\} \setminus \{j_1,j_2,\dots,j_{r-1}\}} \pi_k$$
(75)

$$=\pi_{k_1}+\dots+\pi_{k_r},\tag{76}$$

where the last line comes from the fact that π_i is a normalized fraction of examples containing label *i* in their labels. After the node split, the Precision is defined as the combination of the Precision of its children. For simplicity we consider equal

contribution of each of the edges to $P_{\text{multi}} = \left| \left(\sum_{j=1}^{M} P_j \right) - 1 \right|$. Therefore we can write the Precisions of the children as:

$$(P@r)^{t+1} = (P_1 - \frac{1}{M}P_{\text{multi}})(P@r)^1 + \dots + (P_M - \frac{1}{M}P_{\text{multi}})(P@r)^M$$
(77)

$$= (P_{1} - \frac{1}{M} P_{\text{multi}}) \Big(\max_{i \in \{1, 2, \dots, K\}} \pi_{i} \Big(\frac{P_{1}^{i} - \frac{1}{M} P_{\text{multi}}^{i}}{P_{1} - \frac{1}{M} P_{\text{multi}}} \Big) + \cdots \Big) + \cdots$$
(78)

$$+ (P_{M} - \frac{1}{M}P_{\text{multi}}) \Big(\max_{j \in \{1, 2, \dots, K\}} \pi_{j} \Big(\frac{P_{M}^{i} - \frac{1}{M}P_{\text{multi}}^{i}}{P_{M} - \frac{1}{M}P_{\text{multi}}}\Big) + \cdots \Big)$$

$$= \max_{i \in \{1, 2, \dots, K\}} \pi_{i} \Big(P_{1}^{i} - \frac{1}{M}P_{\text{multi}}^{i}\Big) + \cdots$$
(79)

$$+ \max_{j \in \{1,2,\dots,K\}} \pi_{j} (P_{M}^{j} - \frac{1}{M} P_{\text{multi}}^{j}) + \cdots$$

$$= \frac{1}{M} \Big(\max_{i \in \{1,2,\dots,K\}} \pi_{i} ((M-1)P_{1}^{i} - P_{2}^{i} \cdots - P_{M}^{i} + 1) + \cdots$$

$$+ \max_{i \in \{1,2,\dots,K\}} \pi_{j} ((M-1)P_{M}^{i} - P_{1}^{i} \cdots - P_{M-1}^{i} + 1) + \cdots \Big)$$
(80)

$$= \frac{1}{M} \Big(\max_{i \in \{1,2,\dots,K\}} \pi_i((P_1^i - P_2^i) + (P_1^i - P_3^i) + \dots (P_1^i - P_M^i) + 1) + \dots + \max_{j \in \{1,2,\dots,K\}} \pi_j((P_M^i - P_1^i) + (P_M^i - P_2^i) + \dots (P_M^i - P_{M-1}^i) + 1) + \dots \Big).$$
(81)

Note that the subtraction of $(1/M)P_{\text{multi}}^i$ and $(1/M)P_{\text{multi}}$ in the coefficients is done to compensate the Precision calculation for examples being sent to multiple directions. Let the top r labels assigned to the first child be denoted as $y_r^1(x) = \{i_1, i_2, ..., i_r\}$, where

$$\begin{split} \hat{i}_{1} &= \operatorname{argmax}_{i \in \{1, 2, \dots, K\}} \pi_{i}((P_{1}^{i} - P_{2}^{i}) + (P_{1}^{i} - P_{3}^{i}) + \cdots (P_{1}^{i} - P_{M}^{i})), \\ \hat{i}_{2} &= \operatorname{argmax}_{k \in \{1, 2, \dots, K\} \setminus i_{1}} \pi_{i}((P_{1}^{i} - P_{2}^{i}) + (P_{1}^{i} - P_{3}^{i}) + \cdots (P_{1}^{i} - P_{M}^{i})), \\ \dots, \\ \hat{i}_{r} &= \operatorname{argmax}_{k \in \{1, 2, \dots, K\} \setminus \{i_{1}, \dots, i_{r-1}\}} \pi_{i}((P_{1}^{i} - P_{2}^{i}) + (P_{1}^{i} - P_{3}^{i}) + \cdots (P_{1}^{i} - P_{M}^{i})). \end{split}$$

 $v_r = \operatorname{agmax}_{k \in \{1,2,...,K\} \setminus \{i_1,...,i_{r-1}\}} n_i((1_1 - 1_2) + (1_1 - 1_3) + \cdots + (1_1 - 1_M)).$ Analogy holds for all other children. Thus for example the M^{th} children's labels are: $y_r^M(x) = \{j_1, j_2, ..., j_r\}$. Therefore the difference between the Precision of the parent node and its children can be written as:

$$(P@r)^{t+1} - (P@r)^{t} = \frac{1}{M} \left(\pi_{i_{1}} ((P_{1}^{i_{1}} - P_{2}^{i_{1}}) + \cdots (P_{1}^{i_{1}} - P_{M}^{i_{1}}) + 1) + \cdots \right) + \pi_{i_{r}} ((P_{1}^{i_{r}} - P_{2}^{i_{r}}) + \cdots (P_{1}^{i_{r}} - P_{M}^{i_{r}}) + 1) \right) + \cdots + \frac{1}{M} \left(\pi_{j_{1}} ((P_{M}^{j_{1}} - P_{1}^{j_{1}}) + \cdots (P_{M}^{j_{1}} - P_{M-1}^{j_{1}}) + 1) + \cdots \right) + \pi_{j_{r}} ((P_{M}^{j_{r}} - P_{1}^{j_{r}}) + \cdots (P_{M}^{j_{r}} - P_{M-1}^{j_{r}}) + 1) \right) - (\pi_{k_{1}} + \cdots + \pi_{k_{r}}).$$
(82)

For the ease of notation we show the case for the binary below:

$$(P@r)^{t+1} - (P@r)^{t} = \frac{1}{2} \left(\pi_{i_{1}} (P_{R}^{i_{1}} - P_{L}^{i_{1}} + 1) + \dots + \pi_{i_{r}} (P_{R}^{i_{r}} - P_{L}^{i_{r}} + 1) \right) + \frac{1}{2} \left(\pi_{j_{1}} (P_{L}^{j_{1}} - P_{R}^{j_{1}} + 1) + \dots + \pi_{j_{r}} (P_{L}^{j_{r}} - P_{R}^{j_{r}} + 1) \right) - \left(\pi_{k_{1}} + \dots + \pi_{k_{r}} \right).$$

$$(83)$$

Considering the Assumption 3.1, we have at least one label such that $P_R^k - P_L^k = \gamma_1 > 0, \gamma_1 \in (0, 1]$. Without loss of generality let $P_R^{k_1} - P_L^{k_1} = \gamma_1 > 0$ for the top label in the parent node. Thus: $\pi_{i_1}(P_R^{i_1} - P_L^{i_1} + 1) \ge \pi_{k_1}(1 + \gamma_1)$ and $\pi_{j_1}(P_L^{j_1} - P_R^{j_1} + 1) \ge \pi_{k_1}(1 - \gamma_1)$. Therefore we have $(P@r)^{t+1} - (P@r)^t \ge 0$. Due to the weak hypothesis assumption the histograms in the children nodes are different than in the parent on at least one position corresponding to one label. If that label is in the top r labels that we assign to the children node, the error will be reduced. If not, the error is going to be

the same, but that cannot happen forever, i.e. for some split the label(s) for which the weak hypothesis assumption holds will eventually be in the top r labels that are assigned to the children node. To put this intuition into more formal language, if any of the top r labels in any of the children are different from the top r parent labels, i.e. $y_r^1 \neq y_r, y_r^2 \neq y_r, ...,$ or $y_r^M \neq y_r$ we will have $(P@r)^{t+1} - (P@r)^t > 0$. Because of the weak hypothesis assumption, the latter condition is inevitable and will eventually hold after some node split. This shows that the error is monotonically decreasing.

9 ADDITIONAL ALGORITHMS

Algorithm 3 OptimizeObjective (v) $J_{opt} \leftarrow +\infty$ for $s = 1 \dots 2^M - 1$ do for $m = 1 \dots M$ do $\hat{y}[m] = s \wedge 2^{(m-1)} > 0$ $P_m \leftarrow \frac{(v.C_v - y_i.size())v.P_m + y_i.size() * \hat{y}[m]}{v.C_v}$ for $k \in y_i$ do $P_m^k \leftarrow \frac{(v.l_v[k]-1)v.P_m^k + \hat{y}[m]}{v.l_v[k]}$ end for end for if $J < J_{opt}$ then $J_{opt} \leftarrow J$ $\hat{y}_{opt} \leftarrow \hat{y}$ end if end for return \hat{y}_{opt}

10 EXPERIMENTAL SETUP

LdSM was implemented in C++. The regressors in the tree nodes were trained with either SGD [Bottou (1998)] (Mediamill) or NAG [Ross et al. (2013)] (remaining data sets) with step size chosen from [0.001, 1]. The trees were trained with up to 20 passes through the data and we explored trees with up to 64K nodes for Mediamill and Bibtex, up to 32K for Delicious, and up to 2K for the rest of the data sets. λ_1 and λ_2 were chosen from the set $\{0.5, 1, 1.5, 2, 4\}$ and M was set to either 2 or 4. FastXML, PFastreXML, CRAFTML and LdSM algorithms use tree ensembles of size ~ 50. PLT and LPSR use a single tree, and GBDT-S uses up to 100 trees.

Remark 3 (Training time). The training time of LdSM can be reduced order of magnitudes by using lower number of epochs at the expense of $\sim 1\%$ loss in the accuracy. However, we report the training times that correspond to the best accuracy results obtained with LdSM.

Table 9: Propensity Score Precisions: PSP@1, PSP@3, and PSP@5 (%) and Propensity Score nDCG scores: PSN@1, PSN@3, and PSN@5 (%) obtained by different tree-based methods on common multi-label data sets.

Table 10: Precisions: P@1, P@3, and P@5 (%) and nDCG scores: N@1, N@3, and N@5 (%) obtained for tree-based approaches: GBDT-S, CRAFTML, FastXML, PFastreXML, LPSR, PLT, and LdSM and other (not purely tree-based) methods: Parabel, DisMEC, PD-Sparse, PPD-Sparse, OVA-Primal++, LEML, and SLEEC, on various data sets. The best result among tree-based methods is in bold, and among all methods is underlined.

Figure 4: The behavior of Precision/nDCG score as a function of the number of trees in the ensemble. Plots were obtained for Delicious, Bibtex, Mediamill, and Wiki10 data sets.

Figure 5: The behavior of Precision/nDCG score as a function of the number of nodes T_{max} (including leaves) and tree depth of the deepest tree in the ensemble. Plots were obtained for Delicious, Bibtex, Mediamill, AmazonCat, and Wiki10 data sets.

Figure 6: The comparison of Precision (left column) and nDCG (right column) score for LdSM and FastXML working in the ensemble (right bars) as well as for single-tree (left bars) (LdSM-1: exemplary tree chosen from LdSM ensemble, LdSM-1*, FastXML-1*: optimal single trees). Plots were obtained for Bibtex, Mediamill and Delicious data sets.
