# A Simpler Approach to Accelerated Stochastic Optimization: Iterative Averaging Meets Optimism 

Pooria Joulani ${ }^{* 1}$ Anant Raj ${ }^{* 2}$ András György ${ }^{1}$ Csaba Szepesvári ${ }^{13}$

#### Abstract

Recently there have been several attempts to extend Nesterov's accelerated algorithm to smooth stochastic and variance-reduced optimization. In this paper, we show that there is a simpler approach to acceleration: applying optimistic online learning algorithms and querying the gradient oracle at the online average of the intermediate optimization iterates. In particular, we tighten a recent result of Cutkosky (2019) to demonstrate theoretically that online iterate averaging results in a reduced optimization gap, independently of the algorithm involved. We show that carefully combining this technique with existing generic optimistic online learning algorithms yields the optimal accelerated rates for optimizing strongly-convex and non-strongly-convex, possibly composite objectives, with deterministic as well as stochastic first-order oracles. We further extend this idea to variance-reduced optimization. Finally, we also provide "universal" algorithms that achieve the optimal rate for smooth and non-smooth composite objectives simultaneously without further tuning, generalizing the results of Kavis et al. (2019) and solving a number of their open problems.

## 1. Introduction

Our goal in this paper is to obtain algorithms with optimal convergence rates for the following problem:

$$
\begin{equation*}
\text { find } x^{\star}=\underset{x \in \mathcal{X}}{\operatorname{argmin}} \ell(x)=f(x)+\phi(x), \tag{1}
\end{equation*}
$$

where $\mathcal{X}$ is a convex constraint set in the $d$-dimensional Euclidean space, $f$ is convex and smooth, and $\phi$ is a (possi-

[^0]bly non-smooth) convex function. When $\phi=0$, and given access to (noise-free) gradients of $f$, Nesterov's accelerated gradient algorithms (Nesterov, 2018) achieve optimal rates of convergence for Problem (1). Several recent papers, summarized in Table 1, have attempted to obtain similarly accelerated rates that improve upon the sub-optimal rates of Stochastic Gradient Descent (SGD) when the gradients of $f$ are corrupted by noise and/or when $\phi \neq 0$.

Despite the major effort to obtain these extensions, existing results suffer from several limitations such as: (a) inhibiting noise in the gradient (Allen-Zhu and Orecchia, 2017, Wang and Abernethy, 2018); (b) potentially querying the gradient oracle outside the constraint set (Levy et al., 2018, Cutkosky 2019) (c) not providing optimal rates for strongly-convex objectives (Cutkosky, 2019); (d) extra logarithmic terms appearing in the error bounds (Levy et al., 2018; Cutkosky 2019); (e) not handling proximal updates when $\phi \neq 0$ (Levy et al. 2018, Kavis et al. 2019, Cutkosky, 2019) or (f) relying on prior knowledge of problem parameters (Tseng, 2008; Beck and Teboulle, 2009; Hu et al., 2009; Xiao, 2010; Lan 2012, Chen et al., 2012).

In this paper, we demonstrate a simple direct approach to deriving accelerated rates: following Cutkosky (2019), we propose running an online learning algorithm and feeding it with (possibly noisy) first-order information obtained at the weighted average of its iterates. Then, building on the recent simple, tight modular analysis techniques of generic optimistic online learning algorithms (Joulani et al., 2017; 2020), we are able to alleviate all the aforementioned limitations, design new accelerated algorithms with straightforward convergence analyses, and solve a number of problems left open in previous work.

### 1.1. Contributions and Related Work

Our main contributions can be summarized as follows:

- We provide a direct, simple template for deriving and analyzing accelerated algorithms for stochastic and deterministic convex optimization with composite objectives. We further extend the above framework to variance-reduced stochastic non-strongly-convex optimization.

|  | $\mathcal{X}$ | $f$ | $\phi$ | Oracle | Universal | Notes |

Table 1. Summary of previous work obtaining accelerated rates of convergence. Cutkosky (2019) analyses strongly-convex optimization as well, but the rates are sub-optimal (i.e., non-accelerated). Here, "Non-SC" means non-strongly convex (that is, strong-convexity of $f$ is not required), "SC" means strongly convex, "D" and " S " stand for deterministic and stochastic oracles, respectively. Universality means the algorithm achieves the smooth and non-smooth rates simultaneously without requiring the knowledge of the problem's smoothness and noise level. The "bounded-trajectory" assumption means that the error bound scales with the maximum distance of the iterates from the optimum $x^{\star}$, but the algorithm does not enforce this to be bounded (e.g., through projection to a compact set). See also the survey by Bubeck (2015) and the recent book of Nesterov (2018).

- For composite non-strongly-convex objectives, we provide a new universal algorithm (in the sense of Nesterov, 2015): given only access to the proximal projection oracle of $\phi$ onto the constraint set, without prior knowledge of the smoothness or noise level, the new algorithm simultaneously achieves the optimal rate of convergence for smooth and non-smooth $f$. This, together with the fact that the algorithm uses coordinatewise adaptive step-sizes, resolves two problems left open by Kavis et al. (2019).

In particular, in Lemma 1 and Corollary 2 , we tighten the recent analysis of online iterate averaging by Cutkosky (2019). Compared to their Theorem 1, Corollary 2 exposes additional terms that reduce the optimization gap. These terms, whose absence prevented Cutkosky (2019, Theorem 3) from getting the optimal accelerated rates, are similar to what Wang and Abernethy (2018) obtained through an indirect formulation of acceleration as a two-player game.

Next, we show how to utilize the aforementioned reduction to obtain accelerated rates. This is achieved by using properly-tuned optimistic online learning algorithms
(Rakhlin and Sridharan, 2013a b; Mohri and Yang, 2016) as the underlying optimization machinery. Importantly, this tuning can be done somewhat independently of the assumptions on the objective (such as the presence of noise, strong convexity, or a non-zero $\phi$ ) or the algorithmic techniques (such as proximal updates or adaptive learning rates), thanks to the recent modular analyses of online learning algorithms by Joulani et al. (2017, 2020). This results in a simple, straightforward acceleration framework.

Furthermore, we extend the analysis to variance-reduced optimization for smooth non-strongly-convex functions. We show that incorporating negative momentum (common in the accelerated SVRG literature, see, e.g., Allen-Zhu, 2017, Lan et al. 2019) in our framework introduces an additional reduction in the optimization gap, enabling us to obtain the optimal convergence rate. We also analyze a simpler version of the variance reduced algorithm without negative momentum, which enjoys a variance-reduced, though still sub-optimal rate of convergence for the last iterate.

Finally, we provide a universal algorithm for non-stronglyconvex composite optimization, extending the works of

Levy et al. (2018); Cutkosky (2019); Kavis et al. (2019) to the case when $\phi \neq 0$. The new algorithm features proximal updates and coordinate-wise adaptive step-sizes, thus solving two problems left open by Kavis et al. (2019). Unlike Levy et al. (2018) and Cutkosky (2019), the new algorithm does not query the optimization oracle outside the constraint set $\mathcal{X}$, and does not suffer from extra log terms in the bound. Unlike the algorithm of Kavis et al. (2019) (which is based on mirror-descent) our algorithm is based on dual-averaging, which is better suited to sparse learning with a proximal $\ell_{1}$ penalty (Xiao, 2009; McMahan, 2011).

Notation. $\mathbb{R}$ denotes the set of real numbers. For any positive integer $n,[n]=\{1, \ldots, n\}$. Let $h: \mathcal{D} \rightarrow \mathbb{R}$ where $\mathcal{D} \subset \mathbb{R}^{d}$ for some positive integer $d$. The gradient or a subgradient of $h$ is denoted by $h^{\prime}$. When $h$ is convex, the Bregman-divergence $B_{h}: \mathcal{D} \times \mathcal{D}^{o} \rightarrow \mathbb{R}$ is defined as $B_{h}(x, y)=h(x)-h(y)-\left\langle h^{\prime}(y), x-y\right\rangle$, where $\mathcal{D}^{o}$ denotes the interior of $\mathcal{D}$. We say that $h$ is $\mu$-strongly convex with respect to (w.r.t.) a norm $\|\cdot\|$ if for all $x \in \mathcal{D}, y \in \mathcal{D}^{o}$, $\frac{\mu}{2}\|x-y\|^{2} \leq B_{h}(x, y)$, and it is $\mu$-strongly convex w.r.t. a function $n: \mathcal{D} \times \mathcal{D}^{o} \rightarrow[0, \infty)$ if $\mu \cdot n(x, y) \leq B_{h}(x, y)$ for all $x \in \mathcal{D}, y \in \mathcal{D}^{o}$ (note that $h$ is $\mu$-strongly convex w.r.t. a norm $\|\cdot\|$ if it is $\mu$-strongly convex w.r.t. the function $\|\cdot\|^{2} / 2$ ). For non-negative integers $a, b$ and a sequence of numbers or vectors $x_{0}, x_{1}, \ldots$, we let $x_{a: b}=\sum_{s=a}^{b} x_{s}$ if $a \leq b$ and 0 otherwise. With a slight abuse of notation, for a vector $x \in \mathbb{R}^{d}$, we denote its coordinates as $x=\left(x_{1}, \ldots, x_{d}\right)$; whether the subscript refers to a coordinate or a time index is usually clear from the context (to reduce the possible ambiguity, we normally use $x_{i}$ and $x_{j}$ to index coordinates of $x$, and $x_{t}$ and $x_{s}$ to indicate a quantity corresponding to time steps $t$ or $s$ ). For an event $E, \mathbb{I}\{E\}$ denotes its indicator function, that is $\mathbb{I}\{E\}=1$ if $E$ is true, otherwise $\mathbb{I}\{E\}=0$. The base-2 logarithm of $x \in(0,+\infty)$ is denoted by $\log (x)$.

## 2. Preliminaries

For simplicity, we assume that an optimizer $x^{\star} \in \mathcal{X}$ of Problem (1) exists, i.e., $\ell^{\star}:=\ell\left(x^{\star}\right) \leq \ell(x)$ for all $x \in \mathcal{X} \xrightarrow{1}$

Smoothness of functions. When $f$ is differentiable over $\mathbb{R}^{d}$, given a norm $\|\cdot\|$, the following are equivalent definitions of smoothness of $f$ (Nesterov, 2018, Theorem 2.1.5): $f$ is $L$-smooth if
(i) for all $x, y \in \mathbb{R}^{d}, B_{f}(x, y) \leq \frac{L}{2}\|x-y\|^{2}$;
(ii) for all $x, y \in \mathbb{R}^{d},\left\|f^{\prime}(x)-f^{\prime}(y)\right\|_{*} \leq L\|x-y\|$;
(iii) for all $x, y \in \mathbb{R}^{d}$,

$$
\begin{equation*}
\left\|f^{\prime}(x)-f^{\prime}(y)\right\|_{*}^{2} \leq(2 L) B_{f}(x, y) \tag{2}
\end{equation*}
$$

[^1]Throughout the paper, we only require ${ }^{2}$ that $f$ is differentiable over $\mathcal{X}$, and use (2), holding for all $x, y \in \mathcal{X}$, as the notion of smoothness under which accelerated rates are obtained. Alternatively, assuming (iii) holds only for $x, y \in \mathcal{X}$, one can still obtain the same rates with a very similar analysis as we provide, at the expense of an additional gradient oracle call per step of the algorithms; we leave the details for an extended version of the paper $3^{3}$

Iterative optimization. We consider first-order sequential optimization procedures with access to a stochastic gradient oracle that returns unbiased estimates of $f^{\prime}$. A sequential optimization method then, in iteration $t$, queries the oracle at a point $y_{t} \in \mathcal{X}$, receives a gradient estimate $g_{t}$ such that $\mathbb{E}\left[g_{t} \mid \mathcal{H}_{t}\right]=f^{\prime}\left(y_{t}\right)$ where $\mathcal{H}_{t}=\sigma\left(\left(g_{s}\right)_{s=1}^{t-1},\left(y_{s}\right)_{s=1}^{t}\right)$ is the sigma-algebra generated by all the information used by the algorithm before making the query at $y_{t}$ to the gradient oracle. In case $\phi \neq 0$, we also assume that the optimization method has access to the prox-function of $\phi$ (cf. Eq. 6). After $T$ iterations, the algorithm produces an estimate $\bar{x}_{T}$ of $x^{\star}$, based on all the information it has seen, where the quality of the estimate is measured by the error $\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)\right]-\ell^{\star}$.

Online linear optimization. One way to design and analyze iterative optimization methods is through online linear optimization (OLO) algorithms. An OLO algorithm sequentially comes up, at each time step $t \in[T]$, with a prediction $x_{t}$, then receives a linear loss function $\left\langle\alpha_{t} u_{t}, \cdot\right\rangle$, with the aim of maintaining a small cumulative composite loss $\sum_{t=1}^{T} \alpha_{t}\left(\left\langle u_{t}, x_{t}-x\right\rangle+\phi\left(x_{t}\right)-\phi(x)\right)$, a.k.a. its regret compared to a competitor point $x$. Here $u_{t} \in \mathbb{R}^{d}$ is unknown to the algorithm before selecting $x_{t}$, but the non-negative weights $\alpha_{t}$ are known ahead of time. One can convert an OLO algorithm to an iterative optimization algorithm by using $y_{t}=x_{t}$ to query the oracle, using $u_{t}=g_{t}$ in the linear loss to the OLO algorithm, and employing the average $\bar{x}_{T}=\sum_{t=1}^{T} \frac{\alpha_{t}}{\alpha_{1: T}} x_{t}$ as the final estimate of $x^{\star}$.
The appeal of this "vanilla online-to-batch" approach (Algorithm 11, is that it reduces the convergence analysis of $\bar{x}_{T}$ for convex $f$ and $\phi$ to the regret analysis of the underlying OLO algorithm. In particular, by Jensen's inequality,

$$
\begin{aligned}
& \mathbb{E}\left[\ell\left(\bar{x}_{T}\right)\right]-\ell^{\star} \\
& \leq \sum_{t=1}^{T} \mathbb{E}\left[\frac{\alpha_{t}\left(\left\langle f^{\prime}\left(x_{t}\right), x_{t}-x^{\star}\right\rangle+\phi\left(x_{t}\right)-\phi\left(x^{\star}\right)\right)}{\alpha_{1: T}}\right] \\
& =\mathbb{E}\left[\frac{\sum_{t=1}^{T} \alpha_{t}\left(\left\langle g_{t}, x_{t}-x^{\star}\right\rangle+\phi\left(x_{t}\right)-\phi\left(x^{\star}\right)\right)}{\alpha_{1: T}}\right]
\end{aligned}
$$

[^2]```
Algorithm 1 Vanilla Online-to-Batch
    Input: Stochastic gradient oracle, non-negative weights
    \(\left(\alpha_{t}\right)_{t=1}^{T}\) with \(\alpha_{1}>0\), online linear optimization algo-
    rithm \(\mathcal{A}\)
    Get the initial point \(x_{1} \in \mathcal{X}\) from \(\mathcal{A}\)
    for \(t=1\) to \(T-1\) do
        Get stochastic gradient \(g_{t}\) at the current iterate \(x_{t}\)
        Send \(\left\langle\alpha_{t} g_{t}, \cdot\right\rangle\) as the next linear loss to \(\mathcal{A}\)
        Let \(x_{t+1}\) be the next iterate from \(\mathcal{A}\)
    end for
    return the average iterate \(\frac{\sum_{t=1}^{T} \alpha_{t} x_{t}}{\alpha_{1: T}}\).
```

```
Algorithm 2 Anytime Online-to-Batch (Cutkosky, 2019)
    Input: Stochastic gradient oracle, non-negative weights
    \(\left(\alpha_{t}\right)_{t=1}^{T}\) with \(\alpha_{1}>0\), online linear optimization algo-
    rithm \(\mathcal{A}\)
    Get the initial point \(x_{1} \in \mathcal{X}\) from \(\mathcal{A}\) and let \(\bar{x}_{1} \leftarrow x_{1}\)
    for \(t=1\) to \(T-1\) do
        Get stochastic gradient \(g_{t}\) at the average iterate \(\bar{x}_{t}\)
        Send \(\left\langle\alpha_{t} g_{t}, \cdot\right\rangle\) as the next linear loss to \(\mathcal{A}\)
        Let \(x_{t+1}\) be the next iterate from \(\mathcal{A}\)
        Let \(\bar{x}_{t+1} \leftarrow \frac{\sum_{s=1}^{t+1} \alpha_{s} x_{s}}{\alpha_{1: t+1}}\)
    end for
    return the average iterate \(\bar{x}_{T}\)
```

$$
\begin{equation*}
\leq \mathbb{E}\left[\frac{\mathcal{R}_{T}\left(x^{\star}\right)}{\alpha_{1: T}}\right] \tag{3}
\end{equation*}
$$

where $\mathcal{R}_{T}\left(x^{\star}\right)$ is an upper-bound for the regret of the OLO algorithm. Thus, to analyze the convergence of $\bar{x}_{T}$, one can simply plug-in an off-the-shelf regret bound (reviewed at the end of this section) for the underlying OLO algorithm.

Anytime online-to-batch. An alternative, elegant online-to-batch conversion (Algorithm 2) was recently proposed by Cutkosky (2019), which uses the "online" average $\bar{x}_{t}=$ $\sum_{s=1}^{t} \frac{\alpha_{s}}{\alpha_{1: t}} x_{s}$ as the query point, i.e., $y_{t}=\bar{x}_{t}$. Cutkosky (2019. Theorem 1) showed (with $\phi=0$ ) that (3) holds under this conversion scheme as well. In the next section, we show that in fact Algorithm 2 enjoys a tighter version of (3) that enables us to prove accelerated rates.

Generic regret bound. Next, we recall the regret bound for a general family of OLO algorithms known as "adaptive optimistic follow the regularized leader" or AO-FTRL (Rakhlin and Sridharan, 2013ab; Mohri and Yang, 2016). At time $t$, AO-FTRL makes its $t$-th prediction as

$$
\begin{align*}
x_{t}=\underset{x \in \mathcal{X}}{\operatorname{argmin}}\langle & \left\langle\sum_{s=1}^{t-1} \alpha_{s} g_{s}+\alpha_{t} \tilde{g}_{t}, x\right\rangle \\
& +\alpha_{1: t} \phi(x)+r_{0: t-1}(x), \tag{4}
\end{align*}
$$

where, the $r_{t}: \mathcal{X} \rightarrow \mathbb{R}$ are convex regularizer functions, and for every $t, \tilde{g}_{t}$, the optimistic part of the update, is interpreted as a prediction of $g_{t}$ before it is received.

It is straightforward to see that AO-FTRL captures a wide range of algorithms used in optimization Xiao, 2009, McMahan, 2017). For example, the dual-averaging algorithm of Xiao (2009) corresponds to the case when $\phi=0$ and $r_{0: t-1}=\frac{\eta_{t}}{2}\|\cdot\|_{2}^{2}$ for $\eta_{t}>0$, in which case it is easy to verify that

$$
\begin{equation*}
x_{t}=\Pi_{\mathcal{X}}\left(-\frac{\sum_{s=1}^{t-1} \alpha_{s} g_{s}+\alpha_{t} \tilde{g}_{t}}{\eta_{t}}\right) \tag{5}
\end{equation*}
$$

where $\Pi_{\mathcal{X}}$ denotes Euclidean projection onto set $\mathcal{X}$. More generally, allowing coordinatewise step sizes $\eta_{t} \in[0, \infty)^{d}$ and a possibly non-zero $\phi$, with $r_{0: t-1}(x)=\frac{1}{2} \sum_{j=1}^{d} \eta_{t, j} x_{j}^{2}$ we recover the proximal (a.k.a. "composite-objective" or "regularized") dual-averaging update (Xiao, 2009):

$$
\begin{align*}
x_{t} & =\operatorname{prox}_{\alpha_{1: t} \phi, \eta_{t}}\left(-\sum_{s=1}^{t-1} \alpha_{s} g_{s}-\alpha_{t} \tilde{g}_{t}\right) \\
& =\underset{x \in \mathcal{X}}{\operatorname{argmin}} \alpha_{1: t} \phi(x)+\frac{1}{2} \sum_{j=1}^{d} \eta_{t, j}\left(x_{j}-\frac{z_{t-1, j}}{\eta_{t, j}}\right)^{2}, \tag{6}
\end{align*}
$$

where $\operatorname{prox}_{\alpha_{1: t} \phi, \eta_{t}}$ is the prox-function of $\alpha_{1: t} \phi$ with coordinatewise step sizes $\eta_{t, j}$ and $z_{t-1}=$ $-\left(\sum_{s=1}^{t-1} \alpha_{s} g_{s}+\alpha_{t} \tilde{g}_{t}\right)$. Note that AdaGrad-style updates (Duchi et al. 2011) can be recovered by setting $\eta_{t}$ based on the past gradient estimates $g_{s}, \tilde{g}_{s}$ (for $s<t$ ).
If $r_{t} \geq 0$, the cumulative regularizer $\alpha_{1: t} \phi+r_{0: t-1}$ is $1-$ strongly convex w.r.t. a norm $\|\cdot\|_{(t)}$, and the AO-FTRL update is well-defined, that is, the minimizer $x_{t} \in \mathcal{X}$ exists and $\left\langle\sum_{s=1}^{t-1} \alpha_{s} g_{s}+\alpha_{t} \tilde{g}_{t}, x_{t}\right\rangle+\alpha_{1: t} \phi\left(x_{t}\right)+r_{0: t-1}\left(x_{t}\right)$ is finite, then Theorem 6 of Joulani et al. (2020) gives the following regret bound (see Appendix E]:

$$
\begin{equation*}
\mathcal{R}_{T}\left(x^{\star}\right)=r_{0: T-1}\left(x^{\star}\right)+\sum_{t=1}^{T} \frac{1}{2} \alpha_{t}^{2}\left\|g_{t}-\tilde{g}_{t}\right\|_{(t) *}^{2} \tag{7}
\end{equation*}
$$

## 3. Acceleration with Anytime Online-to-Batch

First, we present a lemma that generalizes the regret decomposition of Joulani et al. (2017) to work with the averaging scheme of Cutkosky (2019). Crucially, the decomposition keeps track of some negative Bregman-divergence terms, which are instrumental in reducing the contribution of the OLO regret to the error of $\bar{x}_{T}$.
Lemma 1. For $t=1,2, \ldots T$, let $\alpha_{t}>0$ and $x_{t} \in \mathbb{R}^{d}$, and define $\bar{x}_{t}=\left(\sum_{s=1}^{t} \alpha_{s} x_{s}\right) / \alpha_{1: t}, B_{t}=\alpha_{t} B_{f}\left(x^{\star}, \bar{x}_{t}\right)$, and $\bar{B}_{t}^{f}=\alpha_{1: t-1} B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right), t>1$. Then, if $\phi$ is convex,

$$
\alpha_{1: T}\left(\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right)
$$

$$
\begin{align*}
& \leq \sum_{t=1}^{T} \alpha_{t}\left(\left\langle f^{\prime}\left(\bar{x}_{t}\right), x_{t}-x^{\star}\right\rangle+\phi\left(x_{t}\right)-\phi\left(x^{\star}\right)\right) \\
& \quad-B_{1: T}-\bar{B}_{2: T}^{f} \tag{8}
\end{align*}
$$

The lemma immediately gives rise to the following generic error bound, which improves upon Theorem 1 of Cutkosky (2019) by keeping around the aforementioned $-\bar{B}_{t}^{f}$ and $-B_{t}$ terms. While the $B_{t}$ are the usual Bregman-divergence terms (also appearing in the vanilla online-to-batch) that are utilized to get fast rates for strongly convex functions (and can be dropped in general as long as the function is star-convex; see Joulani et al. 2020, , the important new terms here are the $-\bar{B}_{t}^{f}$ terms, which allow us to prove accelerated rates for online averaging.
Corollary 2 (Generic Error Bound). Under the assumptions of Lemma 1] if for all $t=1,2, \ldots, T, g_{t} \in \mathbb{R}^{d}$ satisfies $\mathbb{E}\left[g_{t} \mid \bar{x}_{t}\right]=f^{\prime}\left(\bar{x}_{t}\right)$ and we have

$$
\begin{equation*}
\sum_{t=1}^{T} \alpha_{t}\left(\left\langle g_{t}, x_{t}-x^{\star}\right\rangle+\phi\left(x_{t}\right)-\phi\left(x^{\star}\right)\right) \leq \mathcal{R}_{T}\left(x^{\star}\right) \tag{9}
\end{equation*}
$$

for some upper-bound $\mathcal{R}_{T}\left(x^{\star}\right)$, then

$$
\begin{equation*}
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell\left(x^{\star}\right)\right] \leq \mathbb{E}\left[\frac{\mathcal{R}_{T}\left(x^{\star}\right)-B_{1: T}-\bar{B}_{2: T}^{f}}{\alpha_{1: T}}\right] \tag{10}
\end{equation*}
$$

The corollary follows since $g_{t}$ is a conditionally unbiased estimate of $f^{\prime}\left(\bar{x}_{t}\right)$, so the first term on the r.h.s. of (8) is, in expectation, equal to the term on the l.h.s. of (9), and hence upper-bounded by $\mathbb{E}\left[\mathcal{R}_{T}\left(x^{\star}\right)\right]$. Next, we prove the lemma.

Proof of Lemma 1 Writing $f\left(\bar{x}_{T}\right)$ as a telescoping sum,

$$
\begin{aligned}
& f\left(\bar{x}_{T}\right)-f\left(x^{\star}\right) \\
& =-f\left(x^{\star}\right)+\frac{\alpha_{1} f\left(\bar{x}_{1}\right)}{\alpha_{1: T}}+\sum_{t=2}^{T} \frac{\alpha_{1: t} f\left(\bar{x}_{t}\right)-\alpha_{1: t-1} f\left(\bar{x}_{t-1}\right)}{\alpha_{1: T}} \\
& =\sum_{t=1}^{T} \frac{\alpha_{t}\left(f\left(\bar{x}_{t}\right)-f\left(x^{\star}\right)\right)}{\alpha_{1: T}}+\sum_{t=2}^{T} \frac{\alpha_{1: t-1}\left(f\left(\bar{x}_{t}\right)-f\left(\bar{x}_{t-1}\right)\right)}{\alpha_{1: T}} \\
& =\sum_{t=1}^{T} \frac{\alpha_{t}\left\langle f^{\prime}\left(\bar{x}_{t}\right), \bar{x}_{t}-x^{\star}\right\rangle-B_{t}}{\alpha_{1: T}} \\
& \quad+\sum_{t=2}^{T} \frac{\alpha_{1: t-1}\left\langle f^{\prime}\left(\bar{x}_{t}\right), \bar{x}_{t}-\bar{x}_{t-1}\right\rangle-\bar{B}_{t}^{f}}{\alpha_{1: T}} \\
& =\sum_{t=1}^{T} \frac{\alpha_{t}\left\langle f^{\prime}\left(\bar{x}_{t}\right), \bar{x}_{t}-x^{\star}\right\rangle-B_{t}}{\alpha_{1: T}} \\
& \quad+\sum_{t=2}^{T} \frac{\alpha_{t}\left\langle f^{\prime}\left(\bar{x}_{t}\right), x_{t}-\bar{x}_{t}\right\rangle-\bar{B}_{t}^{f}}{\alpha_{1: T}}
\end{aligned}
$$

$=\frac{\sum_{t=1}^{T} \alpha_{t}\left\langle f^{\prime}\left(\bar{x}_{t}\right), x_{t}-x^{\star}\right\rangle-B_{1: T}-\bar{B}_{2: T}^{f}}{\alpha_{1: T}}$,
where the third step follows since by the definition of Bregman divergence, $f(z)-f(y)=\left\langle f^{\prime}(z), z-y\right\rangle-B_{f}(y, z)$, the fourth step follows since by the definition of $\bar{x}_{t}$, for $t=2,3, \ldots, T$ we have $\alpha_{t}\left(\bar{x}_{t}-x_{t}\right)=\alpha_{1: t-1}\left(\bar{x}_{t-1}-\bar{x}_{t}\right)$, and the last step uses $\bar{x}_{1}=x_{1}$. The proof is completed by $\phi\left(\bar{x}_{T}\right)-\phi\left(x^{\star}\right) \leq \sum_{t=1}^{T} \frac{\alpha_{t}}{\alpha_{1: T}}\left(\phi\left(x_{t}\right)-\phi\left(x^{\star}\right)\right)$, which holds by Jensen's inequality.

Acceleration. The main idea behind deriving accelerated rates is combining (7) with (10), and selecting $\alpha_{t}$ and $\tilde{g}_{t}$ appropriately so that the negative terms $-\bar{B}_{t}^{f}$ in (10) offset the contribution of the terms $\frac{\alpha_{t}^{2}}{2}\left\|g_{t}-\tilde{g}_{t}\right\|_{(t) *}^{2}$ in (7) to the final error bound of $\bar{x}_{T}$. For example, let $f$ be $L$-smooth over $\mathbb{R}^{d}$ or assume otherwise that (2) holds with the norm $\|\cdot\|=\|\cdot\|_{2}$. Suppose the optimization algorithm uses the dual averaging update (5) with $\alpha_{t}=t, \eta_{t}=\eta=2 L$, deterministic gradients $g_{t}=f^{\prime}\left(\bar{x}_{t}\right)$, and $\tilde{g}_{t}=g_{t-1}$. Then, $r_{0: t-1}$ is 1-strongly convex w.r.t. the norm $L\|\cdot\|_{2}^{2}$, and the norm terms $\frac{\alpha_{t}^{2}}{2}\left\|g_{t}-\tilde{g}_{t}\right\|_{(t) *}^{2}$ in (7) can be bounded as

$$
\begin{aligned}
\frac{\alpha_{t}^{2}}{2}\left\|g_{t}-\tilde{g}_{t}\right\|_{(t) *}^{2} & =\alpha_{t}^{2} \frac{1}{4 L}\left\|f^{\prime}\left(\bar{x}_{t}\right)-f^{\prime}\left(\bar{x}_{t-1}\right)\right\|_{2}^{2} \\
& \leq \frac{\alpha_{t}^{2}}{2 \alpha_{1: t-1}} \bar{B}_{t}^{f}=\frac{t^{2}}{t(t-1)} \bar{B}_{t}^{f} \leq \bar{B}_{t}^{f}
\end{aligned}
$$

where the first inequality follows using (2). Hence, $\mathcal{R}_{T}\left(x^{\star}\right)-\bar{B}_{2: T}^{f} \leq L\left\|x^{\star}\right\|_{2}^{2}+\frac{1}{4 L}\left\|f^{\prime}\left(x_{1}\right)\right\|_{2}^{2}$. Noticing that $\alpha_{1: T}=\Omega\left(T^{2}\right)$ gives the well-known accelerated $\mathcal{O}\left(1 / T^{2}\right)$ rate for the error of $\bar{x}_{T}$. The next theorem, proved in Appendix A, makes this argument precise for the general setting with noise, non-zero $\phi$ and generic AO-FTRL.
Theorem 3. In Algorithm 2 let the base method $\mathcal{A}$ generate its iterates by the AO-FTRL update (4), using $\tilde{g}_{t}=g_{t-1}$ as the optimistic prediction of $g_{t}$ for $t>1$ and arbitrary $\tilde{g}_{1}$. Suppose that $f$ and $\phi$ are convex, and there exists a norm $\|\cdot\|$ such that either $f$ is 1 -smooth w.r.t. $\|\cdot\|$ over $\mathbb{R}^{d}$ or otherwise (2) holds with $L=1$ for all $x, y \in \mathcal{X}$. Further suppose that for all $t \in[T], r_{t-1} \geq 0$ is convex, the AO-FTRL update (4) is well-defined with finite value at the optimum $x_{t}$, and there exist $\beta_{t}>0$ and a norm $\|\cdot\|_{(t)}$ such that $\alpha_{1: t} \phi+r_{0: t-1}$ is 1-strongly-convex w.r.t. $\frac{\beta_{t}}{2}\|\cdot\|^{2}+\frac{1}{2}\|\cdot\|_{(t)}^{2}$. Then, if $\alpha_{t}^{2} \beta_{t}^{-1} \leq \alpha_{1: t-1}$ for all $t>1$, we have

$$
\begin{align*}
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] \leq & \sum_{t=1}^{T} \mathbb{E}\left[\frac{r_{t-1}\left(x^{\star}\right)-r_{t-1}\left(x_{t}\right)-B_{t}}{\alpha_{1: T}}\right] \\
& +\sum_{t=1}^{T} \mathbb{E}\left[\frac{\alpha_{t}^{2}\left\|\sigma_{t}-\sigma_{t-1}\right\|_{(t) *}^{2}}{2 \alpha_{1: T}}\right] \\
& +\mathbb{E}\left[\frac{\alpha_{1}^{2}\left\|f^{\prime}\left(\bar{x}_{1}\right)-\tilde{g}_{1}\right\|_{*}^{2}}{2 \beta_{1} \alpha_{1: T}}\right] \tag{11}
\end{align*}
$$

where $\sigma_{t}=g_{t}-f^{\prime}\left(\bar{x}_{t}\right), t \in[T]$, and $\sigma_{0}=0$.

## 4. Applications

In this section we use the framework of the previous section, and Theorem 3 in particular, to obtain accelerated convergence rates with proximal updates, noisy gradients, and universal algorithms.

### 4.1. Accelerated Proximal Dual-Averaging

First, we show that with appropriately setting $\alpha_{t}$ and $\eta_{t}$, one can obtain the optimal accelerated rates for the proximal dual averaging update (6). In particular, we consider the case of a single step size for all coordinates (with a slight abuse of notation, $\eta_{t, i}=\eta_{t}$ for all $i$ ) and $r_{0: t-1}=\frac{\eta_{t}}{2}\|\cdot\|_{2}^{2}$. Then, under the conditions of Theorem 3, we have

$$
\begin{align*}
& \mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] \leq \sum_{t=1}^{T} \mathbb{E}\left[\frac{\alpha_{t}^{2}\left\|\sigma_{t}-\sigma_{t-1}\right\|_{(t) *}^{2}}{2 \alpha_{1: T}}\right] \\
& +\mathbb{E}\left[\frac{\eta_{T}\left\|x^{\star}\right\|_{2}^{2}-\sum_{t=1}^{T}\left(\eta_{t}-\eta_{t-1}\right)\left\|x_{t}\right\|_{2}^{2}-2 B_{t}}{2 \alpha_{1: T}}\right] \\
& +\mathbb{E}\left[\frac{\alpha_{1}^{2}}{2 \beta_{1} \alpha_{1: T}}\left\|f^{\prime}\left(\bar{x}_{1}\right)-\tilde{g}_{1}\right\|_{*}^{2}\right] \tag{12}
\end{align*}
$$

Thus, the optimal rates follow immediately by properly setting $\eta_{t}$ and $\alpha_{t}$, as captured by the following corollary.
Corollary 4 (Accelerated Proximal Dual-Averaging). Let $f$ and $\phi$ be convex and assume that either $f$ is $L$-smooth over $\mathbb{R}^{d}$ or otherwise $\sqrt{2}$ holds for all $x, y \in \mathcal{X}$. Consider the online-averaged (stochastic) proximal dual averaging algorithm, given by Algorithm (2) with update (6) using $\tilde{g}_{t}=$ $g_{t-1}$ as the optimistic prediction of $g_{t}$ for $t>1$, and $\tilde{g}_{1}=$ 0 , where the gradient estimates $g_{t}$ are unbiased, that is, $\mathbb{E}\left[g_{t} \mid \bar{x}_{t}\right]=f^{\prime}\left(\bar{x}_{t}\right)$. Let $\sigma_{*}^{2}=\max _{t=1}^{T} \mathbb{E}\left[\left\|\sigma_{t}\right\|_{2}^{2}\right]$, where $\sigma_{t}=g_{t}-f^{\prime}\left(\bar{x}_{t}\right)$, and let $D=\max \left\{\left\|x^{\star}\right\|_{2},\left\|x_{1}-x_{f}^{*}\right\|_{2}\right\}$, where $x_{f}^{*}$ is the minimizer of $f$ over $\mathbb{R}^{d}$. Then we have the following error bounds:
(i) If $\eta_{t}=4 L+\eta \alpha_{t} \sqrt{t}$ for some $\eta>0$ and $\alpha_{t}=t$, we have

$$
\begin{aligned}
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] & \leq \frac{\left(4 L+\frac{L}{4}+\eta T \sqrt{T}\right) D^{2}+\frac{4 \sigma_{*}^{2}}{\eta} T \sqrt{T}}{T(T+1)} \\
& =\mathcal{O}\left(\frac{L D^{2}}{T^{2}}+\frac{\eta D^{2}+\eta^{-1} \sigma_{*}^{2}}{\sqrt{T}}\right)
\end{aligned}
$$

(ii) If $\phi_{t}$ is $\mu$-strongly-convex then using $\eta_{t}=4 L$ and $\alpha_{t}=t$, we have

$$
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] \leq \frac{\left(4 L+\frac{L}{4}\right) D^{2}+\frac{8 \sigma_{*}^{2} T}{\mu}}{T(T+1)}
$$

$$
=\mathcal{O}\left(\frac{L D^{2}}{T^{2}}+\frac{\sigma_{*}^{2}}{\mu T}\right)
$$

(iii) If $g_{t}=f^{\prime}\left(x_{t}\right)$ (i.e., the noiseless case) and $\phi$ is $\mu$ -strongly-convex, then for $\eta_{t}=0$ and any sequence of $\alpha_{t}>0, t \in[T]$ satisfying

$$
\begin{equation*}
\sqrt{c \kappa} \geq \frac{\alpha_{1: t}}{\alpha_{t}} \geq \sqrt{2 \kappa} \quad t>1 \tag{13}
\end{equation*}
$$

for some $c \geq 2$ where $\kappa=(L+\mu) / \mu$ denotes the condition number, we have

$$
\begin{equation*}
\ell\left(\bar{x}_{T}\right)-\ell^{\star} \leq \frac{\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}\left(1-\frac{1}{\sqrt{c \kappa}}\right)^{T-1}}{2 \mu} \tag{14}
\end{equation*}
$$

Remark 1. The above rates of $\mathcal{O}\left(1 / T^{2}\right)$ for a non-strongly-convex $f$ are optimal in $T$ when there is no noise $\left(\sigma_{t}=0\right)$, and the bound 14 also almost matches the optimal $\mathcal{O}\left((1-1 / \sqrt{\kappa})^{T}\right)$ rate for the noiseless stronglyconvex case. When there is noise, the worst-case rate of $\mathcal{O}(1 / \sqrt{T})$ (for non-strongly-convex $f$ ) and $\mathcal{O}(1 / T)$ (for strongly-convex f) are unavoidable, according to the lowerbounds of Nemirovsky and Yudin (1983): when the noise dominates, there is no hope of exploiting the smoothness in the signal (i.e., the gradient). Therefore, similarly to our paper, all previous work obtain only a lower-order improvement, e.g., from $1 / T+\sigma / \sqrt{T}$ (of smooth non-stronglyconvex $S G D$ ) to $1 / T^{2}+\sigma / \sqrt{T}$. If the noise is small, the latter rate is closer to the noise-free optimal rate of $1 / T^{2}$, and determines the convergence speed of the algorithm in the initial stages of optimization. In contrast, the former bound (for $S G D$ ) is sub-optimal in the noise-free case. The possible improvements are lower-order in case of noisy strongly-convex optimization as well.

Proof of Corollary 4 First, notice that with any step size $\eta_{t}=4 L+\gamma_{t}$, the algorithm is equivalent to Algorithm 2 with AO-FTRL as the base algorithm, using regularizers $r_{0: t-1}=\frac{4 L+\gamma_{t}}{2}\|\cdot\|_{2}^{2}$, which satisfy the conditions of Theorem 3 with $\beta_{t}=4,\|\cdot\|^{2}=L\|\cdot\|_{2}^{2}$, and $\|\cdot\|_{(t)}^{2}=$ $\left(\gamma_{t}+\alpha_{1: t} \mu\right)\|\cdot\|_{2}^{2}$, where $\mu$ is the strong-convexity parameter of $\phi$ (i.e, $\mu=0$ in part (ii), and $\mu>0$ in parts (iii) and (iiii). Hence, starting from (12), with $\alpha_{t}=t$ we have

$$
\begin{aligned}
& \mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell\left(x^{\star}\right)\right] \\
& \leq \sum_{t=1}^{T} \frac{t^{2} \mathbb{E}\left[\left\|\sigma_{t}-\sigma_{t-1}\right\|_{2}^{2}\right]}{\left(\gamma_{t}+\alpha_{1: t} \mu\right) T(T+1)}+\frac{\left(4 L+\gamma_{T}\right)\left\|x^{\star}\right\|_{2}^{2}}{T(T+1)} \\
& \quad-\frac{\sum_{t=1}^{T}\left(\gamma_{t}-\gamma_{t-1}\right) \mathbb{E}\left[\left\|x_{t}\right\|_{2}^{2}\right]}{T(T+1)}+\frac{\mathbb{E}\left[\left\|f^{\prime}\left(\bar{x}_{1}\right)\right\|_{2}^{2}\right]}{4 T(T+1) L} .
\end{aligned}
$$

In the above, $\mathbb{E}\left[\left\|\sigma_{t}-\sigma_{t-1}\right\|_{2}^{2}\right] \leq 4 \sigma_{*}^{2}$. In addition, since $f$ is convex and satisfies (2), we have $\frac{1}{2 L}\left\|f^{\prime}\left(\bar{x}_{1}\right)\right\|_{2}^{2} \leq$
$B_{f}\left(x_{1}, x_{f}^{*}\right) \leq \frac{L}{2}\left\|x_{1}-x_{f}^{*}\right\|^{2}$ where $x_{f}^{*}$ is the minimizer of $f$ over $\mathbb{R}^{d}$. Then, plugging in $\gamma_{t}=\eta \alpha_{t} \sqrt{t}$ (respectively, $\gamma_{t}=$ $0)$ and dropping the non-positive terms $-\left(\gamma_{t}-\gamma_{t-1}\right)\left\|x_{t}\right\|_{2}^{2}$ immediately gives part (iip (respectively, part (iii).
To prove part (iii), first recall that for $\eta_{t, j}>0$, (6) is equivalent to the AO-FTRL update (4) with $r_{0: t-1}(x)=$ $\frac{1}{2} \sum_{j=1}^{d} \eta_{t, j} x_{j}^{2}$. For $\eta_{t}=0$, we define the update to be AO-FTRL with $r_{0: t-1}=0$, hence the update will be of the form $x_{t}=\operatorname{argmin}_{x \in \mathcal{X}}\left\langle z_{t-1}, x\right\rangle+\alpha_{1: t} \phi(x)$ (recall that $\left.z_{t-1}=-\sum_{s=1}^{t-1} \alpha_{s} g_{s}-\alpha_{t} \tilde{g}_{t}\right)$. Then, since $\phi$ is stronglyconvex, despite having $r_{s}=0$ for all $s$, we have that $\alpha_{1: t} \phi+r_{0: t-1}$ is strongly-convex w.r.t. $\beta_{t} \frac{L}{2}\|\cdot\|_{2}^{2}$ with $\beta_{t}=\alpha_{1: t} \frac{\mu}{L}$. Hence, by Theorem $33^{4}$ we have

$$
\begin{equation*}
\alpha_{1: T}\left(\ell\left(\bar{x}_{T}\right)-\ell\left(x^{\star}\right)\right) \leq \frac{\alpha_{1}}{2 \mu}\left\|f^{\prime}\left(x_{1}\right)-\tilde{g}_{1}\right\|^{2} \tag{15}
\end{equation*}
$$

as long as for all $t>1$, the assumption $\alpha_{t}^{2} \beta_{t}^{-1} \leq \alpha_{1: t-1}$ of Theorem 3 is satisfied: that is, we have

$$
\begin{equation*}
\frac{\alpha_{t}^{2}}{\alpha_{1: t} \alpha_{1: t-1}} \leq \frac{\mu}{L}=\frac{1}{\kappa-1} \tag{16}
\end{equation*}
$$

It remains to show that is satisfied, and simplify the bound $\sqrt{15}$. To that end, note that on the one hand, by (13) we have $\alpha_{1: t-1} / \alpha_{t} \geq \sqrt{2 \kappa}-1$, which in turn implies $\frac{\alpha_{1: t} \alpha_{1: t-1}}{\alpha_{t}^{2}} \geq 2 \kappa-\sqrt{2 \kappa} \geq \kappa-1$, proving (16). On the other hand, (13) implies $\alpha_{1: t-1} \leq\left(1-\frac{1}{\sqrt{c \kappa}}\right) \alpha_{1: t}$ for all $t>1$; therefore $\alpha_{1} \leq \alpha_{1: T}\left(1-\frac{1}{\sqrt{c \kappa}}\right)^{T-1}$. Putting this back into (15) finishes the proof.

### 4.2. A Proximal Adaptive Universal Algorithm

Next, we present the universal convergence of Algorithm 2 with AdaGrad-style step sizes, proved in Appendix B.
Theorem 5. Suppose that the iterates $x_{t}$ are given by $A O$ FTRL with AdaGrad step sizes, i.e., using (4) with $r_{0}=0$,

$$
r_{t}(x)=\gamma \sum_{j=1}^{d} \frac{\eta_{t, j}-\eta_{t-1, j}}{2}\left(x_{j}-x_{t, j}\right)^{2}, \quad t \geq 1
$$

where $\gamma>0, \eta_{t, j}=\sqrt{\sum_{s=1}^{t} \alpha_{s}^{2}\left(g_{s, j}-\tilde{g}_{s, j}\right)^{2}}, t>0$ and $\eta_{0}=0$. Further suppose that $g_{t}$ are unbiased estimates of $f^{\prime}\left(\bar{x}_{t}\right)$, and we use $\tilde{g}_{t}=g_{t-1}, t>1$ and $\tilde{g}_{1}=0$. Let $R$ be an upper-bound on $\left|x_{j}^{\star}-x_{t, j}\right|^{2}$. Then the following hold:
(i) If $\mathbb{E}\left[g_{t, j}^{2}\right] \leq G_{j}^{2}$ for all $t \in[T]$, then

$$
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] \leq \sum_{j=1}^{d} \mathbb{E}\left[\frac{\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right)}{\alpha_{1: T}} \sqrt{\sum_{t=1}^{T} \alpha_{t}^{2} G_{t, j}^{2}}\right]
$$

[^3]$$
=\mathcal{O}\left(\frac{R \sum_{j=1}^{d} G_{j}}{\sqrt{T}}\right)
$$
for $\gamma=2 / R$, where $G_{t, j}:=\left(g_{t, j}-\tilde{g}_{t, j}\right)$.
(ii) If $f$ is L-smooth over $\mathbb{R}^{d}$ or otherwise (2) holds for all $x, y \in \mathcal{X}$, and $\mathbb{E}\left[\sigma_{t, j}^{2}\right] \leq \sigma_{j}^{2}$ for all $t \in[T]$ (recall that $\left.\sigma_{t}=g_{t}-f^{\prime}\left(\bar{x}_{t}\right)\right)$, then
\[

$$
\begin{aligned}
& \mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] \leq \frac{1}{\alpha_{1: T}} \sum_{j=1}^{d} 6 L\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right)^{2} \\
& \quad+\frac{1}{\alpha_{1: T}}\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right)\left(\Delta+\sum_{j=1}^{d} \sqrt{\sum_{t=1}^{T} 6 \alpha_{t}^{2} \sigma_{j}^{2}}\right) \\
& \quad=\mathcal{O}\left(\frac{L d R^{2}+\Delta R}{T^{2}}+\frac{\max _{j} \sigma_{j} d R}{\sqrt{T}}\right)
\end{aligned}
$$
\]

$$
\text { for } \gamma=2 / R, \text { where } \Delta=\sum_{j=1}^{d} \sqrt{2 \mathbb{E}\left[\left|f^{\prime}\left(x_{1, j}\right)\right|^{2}\right]}
$$

Remark 2. Both bounds above are achieved by the same algorithm, without further prior knowledge about $f$ or the values of $L$ and $\sigma$. The first bound is a data-adaptive bound that holds even if $f$ is non-smooth, and is optimal when the data is sparse (Duchi et al. 2013). The second bound is of the optimal rate $\mathcal{O}\left(1 / T^{2}+\sigma / \sqrt{ } T\right)$ when $f$ is smooth.
Remark 3. The bound $R$ required by the theorem is enforced, e.g., when $\mathcal{X}$ is compact. This implies that in the unconstrained optimization setting, similarly to Levy et al. (2018), we assume that we are still given a compact set $\mathcal{X}$ containing $x^{\star}$ and project to that set in the algorithm.

## 5. Accelerated Variance-Reduced Methods

In this section, we apply our framework to the variance reduced setting. In this setting, we assume $f=\mathbb{E}[F(\cdot, \xi)]$ is the expected value of functions $F: \mathbb{R}^{d} \times \Xi \rightarrow \mathbb{R}$, where $\xi$ is a random variable from some set $\Xi$, with distribution $P_{\Xi}$. At time step $t$, the algorithm receives a realization $\zeta_{t} \sim P_{\Xi}$, and can query the gradient oracle $F^{\prime}\left(\cdot, \zeta_{t}\right)$ at (potentially multiple) points in $\mathcal{X}$. In addition, the algorithm can query the exact (non-stochastic) gradient oracle $f^{\prime}$ from time to time. Then, the gradient estimate $g_{t}$ at $\bar{x}_{t}$ is calculated as

$$
\begin{equation*}
g_{t}=F^{\prime}\left(\bar{x}_{t}, \zeta_{t}\right)-F^{\prime}\left(\tilde{x}_{t}, \zeta_{t}\right)+f^{\prime}\left(\tilde{x}_{t}\right) \tag{17}
\end{equation*}
$$

where $\tilde{x}_{t}$ is the snapshot point at time $t$, i.e., the most recent point at which $f^{\prime}$ has been queried prior to time $t$.
The underlying operational assumption in computing $g_{t}$ is that calls to $F^{\prime}$ are computationally cheaper than calls to $f^{\prime}$, and hence the latter is queried less frequently. This is in particular the case in finite sum minimization problems, where $f=\frac{1}{n} \sum_{i=1}^{n} f_{i}$ for some functions $f_{i}: \mathcal{X} \rightarrow \mathbb{R}$, $F(x, i)=f_{i}(x)$ for all $i \in[n]$, and $\zeta_{t}$ has a uniform distribution over $[n]$. In this case, the computational complexity
of an algorithm is measured by the number of times the gradient of any $f_{i}$ is computed, so a single access to the full gradient oracle $f^{\prime}$ has a computation cost of $\mathcal{O}(n)$.
Let $\mathcal{H}_{1}=\emptyset$ and $\mathcal{H}_{t}=\left\{\zeta_{1}, \zeta_{2}, \ldots, \zeta_{t-1}\right\}$ for $t>1$, i.e., $\mathcal{H}_{t}$ is the history of random realizations up to time $t$. To ensure $g_{t}$ is an unbiased estimate of $f^{\prime}\left(\bar{x}_{t}\right)$, i.e., $\mathbb{E}\left[g_{t} \mid \mathcal{H}_{t}\right]=$ $f^{\prime}\left(\bar{x}_{t}\right)$, we assume that for any $t$ and any $\mathcal{H}_{t}$-measurable $x$,

$$
\begin{align*}
& \mathbb{E}\left[F^{\prime}\left(x, \zeta_{t}\right) \mid \mathcal{H}_{t}\right]=f^{\prime}(x), \text { and }  \tag{18}\\
& \mathbb{E}\left[F\left(x, \zeta_{t}\right) \mid \mathcal{H}_{t}\right]=f(x)
\end{align*}
$$

This is ensured, e.g., if $\zeta_{t}, t=1,2, \ldots$ is an i.i.d. sequence.
Algorithm. In this setting, instead of defining the query point $\bar{x}_{t}$ as the average of the previous outputs of the underlying online optimization algorithm $\mathcal{A}$, we define it as

$$
\begin{equation*}
\bar{x}_{t}=\frac{\alpha_{1: t-1} \bar{x}_{t-1}+\alpha_{t} x_{t}+p_{t} \tilde{x}_{t}}{\alpha_{1: t}+p_{t}} \tag{19}
\end{equation*}
$$

where the $\alpha_{t}>0$ are the averaging weights as before, and $p_{t} \geq 0$ incorporates a negative momentum (first introduced by Allen-Zhu (2017)) towards the current snapshot point $\tilde{x}_{t}$. If $p_{t}=0,19$ reduces back to $\bar{x}_{t}=\frac{1}{\alpha_{1: t}} \sum_{s=1}^{t} \alpha_{s} x_{s}$.
The resulting algorithm, presented in Algorithm 3, extends Algorithm 1 of Joulani et al. (2020) to the anytime averaging scheme with negative momentum. Algorithm 3 operates in epochs (the outer loop in the algorithm goes over the epochs): At the beginning of epoch $s$, the gradient snapshot is calculated. Then, in the $s$ th run of the inner loop, from time $T_{1: s-1}+1$ to $T_{1: s}$, an optimization algorithm $\mathcal{A}$ is run for $T_{s}$ steps with the variance reduced gradient estimates (17) and averaging (19). Finally, the snapshot point is updated at the end of the epoch; the exact form of the update is given later for the different variants we consider.

```
Algorithm 3 Variance-Reduced Anytime Online-to-Batch
with Negative Momentum
    Input: Gradient oracle \(F^{\prime}\) and \(f^{\prime}\), non-negative weights
    \(\left(\alpha_{t}\right)_{t=1}^{T}\) with \(\alpha_{1}>0\), epoch lengths \(T_{1}, T_{2}, \ldots, T_{S}\),
    online linear optimization algorithm \(\mathcal{A}\)
    Get the initial point \(x_{1} \in \mathcal{X}\) from \(\mathcal{A}\)
    \(\tilde{x} \leftarrow x_{1}, \bar{x}_{1} \leftarrow x_{1}\)
    for \(s=1\) to \(S\) do
        Compute and store the full gradient \(f^{\prime}(\tilde{x})\)
        for \(t=T_{1: s-1}+1\) to \(T_{1: s}\) do \(\quad \triangleright\) Denote \(\tilde{x}_{t}=\tilde{x}\)
                Get the gradient estimate \(g_{t}\) at \(\bar{x}_{t}\) by (17)
                Send \(\left\langle\alpha_{t} g_{t}, \cdot\right\rangle\) as the next linear loss to \(\mathcal{A}\)
                Let \(x_{t+1}\) be the next iterate from \(\mathcal{A}\)
                Let \(\bar{x}_{t+1} \leftarrow \frac{\alpha_{1: t} \bar{x}_{t}+\alpha_{t+1} x_{t+1}+p_{t+1} \tilde{x}_{t}}{\alpha_{1: t+1}+p_{t+1}}\)
            end for
        Update the snapshot point \(\tilde{x}\).
    end for
    return the average iterate \(\bar{x}_{T}\) and the latest snapshot \(\tilde{x}\).
```

### 5.1. Warm-Up: No Negative Momentum

First, we consider a version of our accelerated variancereduced method without negative momentum ( $p_{t}=0$ for all $t$ ), using the first iterate of each epoch (i.e., the last iterate of the previous epoch $s-1$ for $s>1$ ) as the snapshot point: In line 12, we let $\tilde{x}=\bar{x}_{t+1}$, so that in every epoch $s \in[S], \tilde{x}_{t}=\bar{x}_{T_{1: s-1}+1}$ for all $t \in\left[T_{1: s-1}+1, T_{1: s}\right]$. We use AO-FTRL with regularizer $r_{1: t-1}=\frac{\eta_{t}}{2}\|\cdot\|_{2}^{2}$ as the underlying algorithm $\mathcal{A}$, with the snapshot used as the optimistic gradient estimate: $\tilde{g}_{t}=f^{\prime}\left(\tilde{x}_{t-1}\right)$. Then, we have the following bound on the performance of the algorithm:
Theorem 6. Suppose that $f$, as well as $F(\cdot, \zeta)$ for all $\zeta \in \Xi$, are a) convex; and, b) either $L$-smooth w.r.t. $\|\cdot\|_{2}$ over $\mathbb{R}^{d}$ or otherwise satisfying (2) for all $x, y \in \mathcal{X}$. Further suppose that 18 holds. Assume that Algorithm 3 is run with epoch lengths $T_{s}=\min \left\{\tau, 2^{s-1}\right\}$ for some maximum epoch length $\tau$, snapshot update $\tilde{x}=\bar{x}_{t+1}$ in line 12, $\alpha_{t}=$ $t$, and $\mathcal{A}$ selected as $A O-F T R L$ with regularizer $r_{1: t-1}=$ $\frac{\eta_{t}}{2}\|\cdot\|_{2}^{2}$ for $\eta_{t}=8 L \tau^{2}$ and optimistic gradient estimates $\tilde{g}_{1}=0$ and $\tilde{g}_{t}=f^{\prime}\left(\tilde{x}_{t-1}\right), t>1$. Then, for any $T>\tau$,

$$
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)\right]-\ell\left(x^{\star}\right) \leq \frac{8 L \tau^{2}\left\|x^{\star}\right\|_{2}^{2}+\frac{\left\|f^{\prime}\left(\bar{x}_{1}\right)\right\|_{2}^{2}}{8 L \tau^{2}}}{T(T+1)}
$$

Proof. By Theorem 17 in Appendix E,

$$
\mathcal{R}_{T}\left(x^{\star}\right)=\frac{\eta_{T}}{2}\left\|x^{\star}\right\|_{2}^{2}+\sum_{t=1}^{T} \frac{\alpha_{t}^{2}}{2 \eta_{t}}\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2}
$$

bounds the linearized composite-objective regret of $\mathcal{A}$. Combining with Corollary 2 and using $B_{1: T} \geq 0$,

$$
\begin{aligned}
& \mathbb{E}\left[\ell\left(\bar{x}_{T}\right)\right]-\ell\left(x^{\star}\right) \\
& \leq \frac{1}{\alpha_{1: T}} \mathbb{E}\left[\frac{\eta_{T}}{2}\left\|x^{\star}\right\|_{2}^{2}+\sum_{t=1}^{T} \frac{\alpha_{t}^{2}}{2 \eta_{t}}\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2}-\bar{B}_{2: T}^{f}\right]
\end{aligned}
$$

Lemma 9 in Appendix Chows that

$$
\sum_{t=2}^{T} \alpha_{t}^{2}\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2} \leq 16 L \tau^{2} \bar{B}_{2: T}^{f}
$$

which then can be used to cancel all terms but $\| g_{1}-$ $\tilde{g}_{1} \|_{2}^{2} /\left(2 \eta_{1}\right)$ from the summation above. Using $g_{1}=f^{\prime}\left(\bar{x}_{1}\right)$ and $\tilde{g}_{1}=0$, and substituting $\eta_{t}$ finishes the proof.

In the finite sum optimization setting, by selecting $\tau=n$, our algorithm achieves $\varepsilon$ error after $\mathcal{O}\left(n \log n+n \sqrt{\frac{L}{\varepsilon}}\right)$ individual gradient evaluations, via a simple direct approach. More complicated methods, such as Catalyst (Lin et al., 2015), RPDG (Lan and Zhou, 2018), Katyusha (AllenZhu, 2017) and related papers achieve an iteration complexity of $\mathcal{O}\left(n \log \frac{1}{\varepsilon}+\sqrt{\frac{n L}{\varepsilon}}\right)$, which has a better dependence on $n$ in the dominant second term. However, these
methods use an indirect approach (as termed by Allen-Zhu (2017)), where non-strongly-convex functions are optimized by adding strongly-convex perturbations, and yet do not achieve the near-optimal rate of Lan et al. (2019), which is obtained using negative momentum and epoch averaging. In the next section, we obtain this near-optimal bound.

### 5.2. Improved Variance-Reduced Acceleration

In this section, we use negative momentum to achieve a nearoptimal accelerated variance-reduced rate: we set $p_{t}>0$ in Algorithm 3. In addition, unlike Theorem6, the snapshot point at the end of epoch $s$ is now given by an average:

$$
\begin{equation*}
\tilde{x}_{s+1}=\frac{1}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} p_{t}} \sum_{t=T_{1: s-1}+1}^{T_{1: s}} p_{t} \bar{x}_{t} \tag{20}
\end{equation*}
$$

For simplicity, we assume $\phi=0$, so that $\ell=f$.
A consequence of computing $\bar{x}_{t}$ via with $p_{t}>0$ is that for all $t=1,2, \ldots, T$,

$$
\begin{equation*}
\alpha_{t}\left(\bar{x}_{t}-x_{t}\right)=\alpha_{1: t-1}\left(\bar{x}_{t-1}-\bar{x}_{t}\right)+p_{t}\left(\tilde{x}_{t}-\bar{x}_{t}\right) . \tag{21}
\end{equation*}
$$

Then, we will have the following error decomposition.
Lemma 7 (Regret Decomposition). For $t \in[T]$, let $\alpha_{t}, p_{t}>0, x_{t}, \tilde{x}_{t} \in \mathbb{R}^{d}$, and define $\bar{x}_{t}$ as in Equation (19), $B_{t}=\alpha_{t} B_{f}\left(x^{\star}, \bar{x}_{t}\right)$ and $\bar{B}_{t}^{f}=\alpha_{1: t-1} B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right)$. Then, for all $x^{\star} \in \mathbb{R}^{d}$,

$$
\begin{align*}
& f\left(\bar{x}_{T}\right)-f^{\star}=\frac{1}{\alpha_{1: T}}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), x_{t}-x^{\star}\right\rangle-B_{1: T}\right. \\
& \left.-\sum_{t=2}^{T} \bar{B}_{t}^{f}+\sum_{t=1}^{T} p_{t}\left(f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)-B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)\right)\right] \tag{22}
\end{align*}
$$

The above error decomposition, proved in Appendix D, is similar to Lemma 1, but has an extra term due to the negative momentum, which will be helpful in further reducing the error. Then, the next theorem, proved in Appendix D, provides the improved convergence rate.
Theorem 8. Consider the conditions of Theorem 6 but instead suppose that the snapshot update in Line 12 of Algorithm 3 is given by 20), $\tilde{g}_{t}=g_{t-1}, t>1$, we use $p_{t}$ such that $0<p_{1} \leq 1$ and $p_{t} \geq \frac{15 L \alpha_{t}^{2}}{\eta_{t}}, t \geq 1$, and we set $\eta_{t}=1860 L T_{s(t)} \log (2 t)$, where $s(t)$ denotes the epoch containing iteration $t$. Then, for any $T \geq 1$,
$\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)\right]-\ell\left(x^{\star}\right) \leq$
$\frac{3720 L T_{s(T)}\left\|x^{\star}\right\|_{2}^{2}+\frac{\left\|f^{\prime}\left(\bar{x}_{1}\right)\right\|_{2}^{2}}{930 L \log 2}+4\left(f\left(\tilde{x}_{1}\right)-f^{\star}\right)}{T^{2}} \log (2 T)$.
The rate provided in Theorem 8 is optimal up to a logarithmic factor. In particular, for the finite sum setting, with
$\tau=n$, the algorithm needs $\tilde{\mathcal{O}}\left(n \log n+\sqrt{\frac{n L}{\varepsilon}}\right)$ individual gradient evaluations to reach $\varepsilon$ error, matching the rate recently obtained by Lan et al. (2019). Unlike in previous work, our convergence guarantee holds for the last iterate instead of a snapshot point or the average of the last epoch.

## 6. Conclusions

We demonstrated that online iterate averaging combined with optimistic online learning can lead to accelerated rates in several scenarios. The resulting algorithms and their analyses are surprisingly simple and often yield the optimal rates. Exploring the full power of this method is left for future work. In particular, it would be interesting to extend this approach to obtain accelerated exponential rates for variance-reduced optimization of strongly-convex objectives, and remove the extra logarithmic terms in the non-strongly-convex variance-reduction case.

## A. Proof of Theorem 3

Proof of Theorem 3 First, we bound the linear composite regret $\sum_{t=1}^{T} \alpha_{t}\left(\left\langle g_{t}, x_{t}-x^{\star}\right\rangle+\phi\left(x_{t}\right)-\phi\left(x^{\star}\right)\right)$ by a bound $\mathcal{R}_{T}$ that results in slightly better constants compared to (7). For $t \in[T]$, let $u_{t}, v_{t}$ be any two vectors such that $g_{t}-\tilde{g}_{t}=u_{t}+v_{t}$, and define $D_{t}=r_{t-1}\left(x^{\star}\right)-r_{t-1}\left(x_{t}\right)$. Then, Theorem 17 bounds the regret of the AO-FTRL updates made by $\mathcal{A}$ as follows:

$$
\begin{align*}
& \sum_{t=1}^{T}\left(\left\langle\alpha_{t} g_{t}, x_{t}-x^{\star}\right\rangle+\alpha_{t} \phi\left(x_{t}\right)-\alpha_{t} \phi\left(x^{\star}\right)\right)-D_{1: T} \\
& \leq \sum_{t=1}^{T}\left(\alpha_{t}\left\langle g_{t}-\tilde{g}_{t}, x_{t}-x_{t+1}\right\rangle-B_{\alpha_{1: t} \phi+r_{0: t-1}}\left(x_{t+1}, x_{t}\right)\right) \\
& \leq \sum_{t=1}^{T}\left(\left\langle\alpha_{t} u_{t}+\alpha_{t} v_{t}, x_{t}-x_{t+1}\right\rangle-\frac{\beta_{t}}{2}\left\|x_{t}-x_{t+1}\right\|^{2}-\frac{1}{2}\left\|x_{t}-x_{t+1}\right\|_{(t)}^{2}\right) \\
& \leq \sum_{t=1}^{T} \frac{\alpha_{t}^{2}\left\|v_{t}\right\|_{(t) * *}^{2}}{2}+\sum_{t=1}^{T} \frac{\alpha_{t}^{2}\left\|u_{t}\right\|_{*}^{2}}{2 \beta_{t}}, \tag{23}
\end{align*}
$$

where the second step uses the strong-convexity of $\alpha_{1: t} \phi+r_{0: t-1}$, and the third step follows by the Fenchel-Young inequality $\langle z, x\rangle-\frac{\beta}{2}\|x\|^{2} \leq \frac{1}{2 \beta}\|z\|_{*}^{2}$. Now, let $u_{1}=f^{\prime}\left(\bar{x}_{1}\right)-\tilde{g}_{1}, u_{t}=f^{\prime}\left(\bar{x}_{t}\right)-f^{\prime}\left(\bar{x}_{t-1}\right), t=2, \ldots, T$, and $v_{t}=\sigma_{t}-\sigma_{t-1}, t \in[T]$, and notice that for all $t=2, \ldots, T$,

$$
\begin{align*}
\frac{\alpha_{t}^{2}\left\|u_{t}\right\|_{*}^{2}}{2 \beta_{t}} & \leq \frac{\alpha_{1: t-1}\left\|u_{t}\right\|_{*}^{2}}{2}=\frac{\alpha_{1: t-1}}{2}\left\|f^{\prime}\left(\bar{x}_{t}\right)-f^{\prime}\left(\bar{x}_{t-1}\right)\right\|_{*}^{2} \\
& \leq \alpha_{1: t-1} B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right)=\bar{B}_{t}^{f} \tag{24}
\end{align*}
$$

using the assumption of $\alpha_{t}^{2} \beta_{t}^{-1} \leq \alpha_{1: t-1}$ and (2) with $L=1$. Plugging the definitions of $u_{t}$ and $v_{t}$ into (23) and using (24, we obtain

$$
\begin{align*}
& \sum_{t=1}^{T}\left\langle\alpha_{t} g_{t}, x_{t}-x^{\star}\right\rangle \leq \sum_{t=1}^{T}\left(D_{t}+\alpha_{t} \phi\left(x_{t}\right)-\alpha_{t} \phi\left(x^{\star}\right)\right) \\
& +\sum_{t=1}^{T} \frac{\alpha_{t}^{2}\left\|\sigma_{t}-\sigma_{t-1}\right\|_{(t) *}^{2}}{2}+\frac{\alpha_{1}^{2}\left\|f^{\prime}\left(\bar{x}_{1}\right)-\tilde{g}_{1}\right\|_{*}^{2}}{2 \beta_{1}}+\bar{B}_{2: T}^{f} \tag{25}
\end{align*}
$$

Applying Corollary 2, combining with 25, and cancelling the matching $\bar{B}_{2: T}$ terms concludes the proof.

## B. Proof of Theorem 5

Proof of Theorem 5 Starting from Lemma 1 , we plug-in the bound of composite AO-FTRL from Mohri and Yang 2016, Theorem 3) (using $f_{t} \leftarrow\left\langle\alpha_{t} g_{t}, \cdot\right\rangle$ ):

$$
\begin{aligned}
\sum_{t=1}^{T} \alpha_{t}\left(\left\langle g_{t}, x_{t}-x^{\star}\right\rangle+\phi\left(x_{t}\right)-\phi\left(x^{\star}\right)\right) & \leq r_{0: T}\left(x^{\star}\right)+\sum_{t=1}^{T} \alpha_{t}^{2}\left\|g_{t}-\tilde{g}_{t}\right\|_{(t) *}^{2} \\
& \leq \frac{\gamma R^{2}}{2} \sum_{j=1}^{d} \sqrt{\sum_{t=1}^{T} \alpha_{t}^{2}\left(g_{t, j}-\tilde{g}_{t, j}\right)^{2}}+\frac{1}{\gamma} \sum_{j=1}^{d} \sum_{t=1}^{T} \frac{\alpha_{t}^{2}\left(g_{t, j}-\tilde{g}_{t, j}\right)^{2}}{\sqrt{\sum_{s=1}^{t} \alpha_{s}^{2}\left(g_{s, j}-\tilde{g}_{s, j}\right)^{2}}} \\
& \leq\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right) \sum_{j=1}^{d} \sqrt{\sum_{t=1}^{T} \alpha_{t}^{2}\left(g_{t, j}-\tilde{g}_{t, j}\right)^{2}}
\end{aligned}
$$

where the first inequality follows from Mohri and Yang 2016. Theorem 3) with the norm $\|y\|_{(t) *}=\sum_{j=1}^{d} \frac{1}{\gamma \eta_{t, j}}\left(y_{j}\right)^{2}$, the second from the definitions using $r_{0: T} \leq \sum_{t=1}^{T} \sum_{j=1}^{d} \frac{\gamma R^{2}}{2}\left(\eta_{t, j}-\eta_{t-1, j}\right)=\sum_{j=1}^{d} \frac{\gamma R^{2}}{2} \eta_{T, j}$, and the third from the standard inequality that $\sum_{t=1}^{T} a_{t} / \sqrt{a_{1: t}} \leq 2 \sqrt{a_{1: T}}$.

Putting back into Corollary2, we obtain

$$
\begin{equation*}
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] \leq \frac{1}{\alpha_{1: T}} \mathbb{E}\left[\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right) \sum_{j=1}^{d} \sqrt{\sum_{t=1}^{T} \alpha_{t}^{2}\left(g_{t, j}-\tilde{g}_{t, j}\right)^{2}}-\bar{B}_{2: T}^{f}\right] \tag{26}
\end{equation*}
$$

Dropping the negative terms $\bar{B}_{2: T}^{f}$, using Jensen's inequality to take the expectation under the square-root, using $\alpha_{t}=t$ and applying the bound $G_{j}$ completes the proof of the first part of the theorem.

To prove the second part, observe that for $t>1$, because $\tilde{g}_{t}=g_{t-1}$, we have

$$
\left|g_{t, j}-\tilde{g}_{t, j}\right|=\left|f_{j}^{\prime}\left(\bar{x}_{t}\right)+\sigma_{t, j}-f_{j}^{\prime}\left(\bar{x}_{t-1}\right)-\sigma_{t-1, j}\right| \leq\left|\sigma_{t, j}\right|+\left|\sigma_{t-1, j}\right|+\left|f_{j}^{\prime}\left(\bar{x}_{t}\right)-f_{j}^{\prime}\left(\bar{x}_{t-1}\right)\right|
$$

Now, denote $\Delta_{1, j}=\left|f_{j}^{\prime}\left(\bar{x}_{1}\right)\right|$ and $\Delta_{t, j}=\left|f_{j}^{\prime}\left(\bar{x}_{t}\right)-f_{j}^{\prime}\left(\bar{x}_{t-1}\right)\right|, t>1$. By Jensen's inequality, $(a+b+c)^{2} \leq 3\left(a^{2}+b^{2}+c^{2}\right)$ for any real numbers $a, b, c$. In addition, for $t>1, \sum_{j=1}^{d} \Delta_{t, j}^{2}=\left\|f^{\prime}\left(\bar{x}_{t}\right)-f^{\prime}\left(\bar{x}_{t-1}\right)\right\|_{2}^{2} \leq 2 L B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right)$ by (2). Hence,

$$
\begin{equation*}
\sum_{t=2}^{T} \alpha_{t}^{2}\left(g_{t, j}-\tilde{g}_{t, j}\right)^{2} \leq \sum_{t=2}^{T} 3 \alpha_{t}^{2}\left[\sigma_{t, j}^{2}+\sigma_{t-1, j}^{2}+\Delta_{t, j}^{2}\right] \tag{27}
\end{equation*}
$$

on the one hand, and on the other hand

$$
-\bar{B}_{2: T}^{f} \leq-\sum_{j=1}^{d} \sum_{t=2}^{T} \frac{\alpha_{1: t-1}}{2 L} \Delta_{t, j}^{2}
$$

Next, using $\alpha_{1}=1$ and $\tilde{g}_{1}=0$, we have $\alpha_{1}^{2}\left(g_{1, j}-\tilde{g}_{1, j}\right)^{2} \leq 2 \sigma_{1, j}^{2}+2 \Delta_{1, j}^{2}$ by Jensen's inequality. Putting back into 26,

$$
\begin{aligned}
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] \leq & \frac{1}{\alpha_{1: T}}\left[\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right) \sum_{j=1}^{d} \mathbb{E}\left[\sqrt{2 \sigma_{1, j}^{2}+2 \Delta_{1, j}^{2}+\sum_{t=2}^{T} 3 \alpha_{t}^{2}\left[\sigma_{t, j}^{2}+\sigma_{t-1, j}^{2}+\Delta_{t, j}^{2}\right]}\right]-\mathbb{E}\left[\bar{B}_{2: T}^{f}\right]\right] \\
\leq & \frac{1}{\alpha_{1: T}} \sum_{j=1}^{d}\left[\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right) \sqrt{\sum_{t=1}^{T} 6 \alpha_{t}^{2} \sigma_{j}^{2}+2 \mathbb{E}\left[\Delta_{1, j}^{2}\right]+\sum_{t=2}^{T} 3 \alpha_{t}^{2} \mathbb{E}\left[\Delta_{t, j}^{2}\right]}-\sum_{t=2}^{T} \frac{\alpha_{1: t-1}}{2 L} \mathbb{E}\left[\Delta_{t, j}^{2}\right]\right] \\
\leq & \frac{1}{\alpha_{1: T}} \sum_{j=1}^{d}\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right) \sqrt{\sum_{t=1}^{T} 6 \alpha_{t}^{2} \sigma_{j}^{2}+2 \mathbb{E}\left[\Delta_{1, j}^{2}\right]} \\
& +\frac{1}{\alpha_{1: T}} \sum_{j=1}^{d}\left[\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right) \sqrt{24 L \sum_{t=2}^{T} \frac{\alpha_{1: t-1}}{2 L} \mathbb{E}\left[\Delta_{t, j}^{2}\right]-\sum_{t=2}^{T} \frac{\alpha_{1: t-1}}{2 L} \mathbb{E}\left[\Delta_{t, j}^{2}\right]}\right]
\end{aligned}
$$

using in the second step the concavity of the square root, Jensen's inequality and the upper-bound $\mathbb{E}\left[\sigma_{s, j}^{2}\right] \leq \sigma_{j}, s \geq 1$, and in the last step $\alpha_{t}=t$ and the fact that for $t>1, \frac{\alpha_{t}^{2}}{\alpha_{1: t-1}} \leq 4$. Next, we note that for $a, b \geq 0,2 \sqrt{a b}-b \leq a$. Therefore,

$$
\begin{aligned}
\mathbb{E}\left[\ell\left(\bar{x}_{T}\right)-\ell^{\star}\right] \leq & \frac{1}{\alpha_{1: T}} \sum_{j=1}^{d}\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right) \sqrt{\sum_{t=1}^{T} 6 \alpha_{t}^{2} \sigma_{j}^{2}+2 \mathbb{E}\left[\Delta_{1, j}^{2}\right]} \\
& +\frac{1}{\alpha_{1: T}} \sum_{j=1}^{d} 6 L\left(\frac{\gamma R^{2}}{2}+\frac{2}{\gamma}\right)^{2} .
\end{aligned}
$$

Separating the first square-root and using $\Delta=\sum_{j=1}^{d} \sqrt{2 \mathbb{E}\left[\Delta_{1, j}^{2}\right]}$ completes the proof of the second part.

## C. Variance reduction for smooth functions

Lemma 9. Suppose the assumptions of Theorem 6 hold. Then

$$
\sum_{t=2}^{T} \alpha_{t}^{2} \mathbb{E}\left[\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2}\right] \leq 16 L \tau^{2} \bar{B}_{2: T}^{f}
$$

Proof. Fix time step $t>1$ within epoch $s>1$ (recall there is only one step, $t=1$, in epoch $s=1$ ). We consider two cases:
a) Time step $t$ is the first time step in epoch $s$ :

This implies that $t=T_{1: s-1}+1$. In addition, $\tilde{x}_{t}=\bar{x}_{t}$ by definition, and $\tilde{x}_{t-1}=\bar{x}_{t^{\prime}}$ where $t^{\prime}=T_{1: s-2}+1$ is the first iterate of epoch $s-1$. Then,

$$
\begin{aligned}
\mathbb{E}\left[\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2} \mid \mathcal{H}_{t}\right] & =\mathbb{E}\left[\left\|F^{\prime}\left(\bar{x}_{t}, \zeta_{t}\right)-F^{\prime}\left(\tilde{x}_{t}, \zeta_{t}\right)+f^{\prime}\left(\tilde{x}_{t}\right)-f^{\prime}\left(\tilde{x}_{t-1}\right)\right\|_{2}^{2} \mid \mathcal{H}_{t}\right] \\
& =\left\|f^{\prime}\left(\tilde{x}_{t}\right)-f^{\prime}\left(\tilde{x}_{t-1}\right)\right\|_{2}^{2}=\left\|f^{\prime}\left(\bar{x}_{t}\right)-f^{\prime}\left(\bar{x}_{t^{\prime}}\right)\right\|_{2}^{2} \\
& =\left\|\sum_{k=T_{1: s-2}+1}^{T_{1: s-1}}\left(f^{\prime}\left(\bar{x}_{k+1}\right)-f^{\prime}\left(\bar{x}_{k}\right)\right)\right\|_{2}^{2} \\
& \leq T_{s-1} \sum_{k=T_{1: s-2}+1}^{T_{1: s-1}}\left\|\left(f^{\prime}\left(\bar{x}_{k+1}\right)-f^{\prime}\left(\bar{x}_{k}\right)\right)\right\|_{2}^{2} \\
& \leq 2 L \tilde{\tau}_{t} \sum_{k=t-\tilde{\tau}_{t}+1}^{t} B_{f}\left(\bar{x}_{k}, \bar{x}_{k-1}\right),
\end{aligned}
$$

where the first inequality follows by Jensen's inequality and the convexity of $\|\cdot\|^{2}$, and the second inequality follows because the smoothness assumption on that implies (2) holds for $f$ and any $x, y \in \mathcal{X}$, and we substitute $\tilde{\tau}_{t}:=T_{s-1}$.
b) Time step $t$ is not the first time step in epoch $s$ :

In this case, let $\tilde{\tau}_{t}=t-\left(T_{1: s-1}+1\right)>0$ denote the number of time steps elapsed since the beginning of the epoch, so that $\tilde{x}_{t-1}=\tilde{x}_{t}=\bar{x}_{t-\tilde{\tau}_{t}}$. Then,

$$
\begin{aligned}
\mathbb{E}\left[\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2} \mid \mathcal{H}_{t}\right] & =\mathbb{E}\left[\left\|F^{\prime}\left(\bar{x}_{t}, \zeta_{t}\right)-F^{\prime}\left(\tilde{x}_{t}, \zeta_{t}\right)+f^{\prime}\left(\tilde{x}_{t}\right)-f^{\prime}\left(\tilde{x}_{t-1}\right)\right\|_{2}^{2} \mid \mathcal{H}_{t}\right] \\
& =\mathbb{E}\left[\left\|F^{\prime}\left(\bar{x}_{t}, \zeta_{t}\right)-F^{\prime}\left(\bar{x}_{t-\tilde{\tau}_{t}}, \zeta_{t}\right)\right\|_{2}^{2} \mid \mathcal{H}_{t}\right] \\
& =\mathbb{E}\left[\left.\left\|\sum_{k=t-\tilde{\tau}_{t}+1}^{t}\left(F^{\prime}\left(\bar{x}_{k}, \zeta_{t}\right)-F^{\prime}\left(\bar{x}_{k-1}, \zeta_{t}\right)\right)\right\|_{2}^{2}\right|_{\mathcal{H}_{t}}\right] \\
& \leq \tilde{\tau}_{t} \sum_{k=t-\tilde{\tau}_{t}+1}^{t} \mathbb{E}\left[\left\|\left(F^{\prime}\left(\bar{x}_{k}, \zeta_{t}\right)-F^{\prime}\left(\bar{x}_{k-1}, \zeta_{t}\right)\right)\right\|_{2}^{2} \mid \mathcal{H}_{t}\right] \\
& \leq 2 \tilde{\tau}_{t} L \sum_{k=t-\tilde{\tau}_{t}+1}^{t} \mathbb{E}\left[B_{F\left(\cdot, \zeta_{t}\right)}\left(\bar{x}_{k-1}, \bar{x}_{k}\right) \mid \mathcal{H}_{t}\right] \\
& =2 \tilde{\tau}_{t} L \sum_{k=t-\tilde{\tau}_{t}+1}^{t} B_{f}\left(\bar{x}_{k-1}, \bar{x}_{k}\right)
\end{aligned}
$$

where the last inequality follows from the smoothness assumption that ensures 2 holds for $F\left(\cdot, \zeta_{t}\right)$ and any $x, y \in \mathcal{X}$, and the last equality follows by 18 .
Multiplying by $\alpha_{t}^{2}$ and summing up for all $t$, we get

$$
\sum_{t=2}^{T} \alpha_{t}^{2} \tilde{\tau}_{t} \sum_{k=t-\tilde{\tau}_{t}+1}^{t} B_{f}\left(\bar{x}_{k-1}, \bar{x}_{k}\right)=\sum_{k=2}^{T} B_{f}\left(\bar{x}_{k-1}, \bar{x}_{k}\right) \sum_{t=2}^{T} \alpha_{t}^{2} \tilde{\tau}_{t} \mathbb{I}\left\{t-\tilde{\tau}_{t}+1 \leq k \leq t\right\}
$$

Next, recall that by definition, $T_{s}=\min \left(\tau, 2^{s-1}\right) \leq T_{1: s-1}+1$ for any $s \geq 1$. Therefore, in case (a) above, $t=$ $T_{1: s-2}+T_{s-1}+1 \leq 2 T_{1: s-2}+2=2\left(t-\tilde{\tau}_{t}\right)$. Similarly, in case (b) above, $t \leq T_{1: s} \leq 2 T_{1: s-1}+1 \leq 2\left(t-\tilde{\tau}_{t}\right)$. Thus, using $\alpha_{t}=t$,

$$
\sum_{t=2}^{T} \alpha_{t}^{2} \tilde{\tau}_{t} \mathbb{I}\left\{t-\tilde{\tau}_{t}+1 \leq k \leq t\right\} \leq \alpha_{2 k-2}^{2} \sum_{t=2}^{T} \tilde{\tau}_{t} \mathbb{I}\left\{k \leq t \leq k+\tilde{\tau}_{t}-1\right\} \leq 4 \tau^{2}(k-1)^{2} \leq 8 \tau^{2} \alpha_{1: k-1}
$$

using in the first step the fact that $t \leq 2\left(t-\tilde{\tau}_{t}\right) \leq 2(k-1)$ by the argument above and the condition inside the indicator (which we also re-arranged), and in the second step $\alpha_{t}=t$ and $\tilde{\tau}_{t} \leq T_{s} \leq \tau$. Combining the above, we get

$$
\sum_{t=2}^{T} \alpha_{t}^{2} \mathbb{E}\left[\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2}\right] \leq 16 L \tau^{2} \sum_{t=2}^{T} \alpha_{1: t-1} B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right)=16 L \tau^{2} \bar{B}_{2: T}^{f}
$$

finishing the proof.

## D. Improved variance-reduced rate for smooth functions

Proof of Lemma 7 The proof follows similar steps as the proof of Lemma 1, with the difference that we need to handle the negative momentum term as well:

$$
\begin{align*}
f\left(\bar{x}_{T}\right)-f^{\star} & =\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T} \alpha_{t} f\left(\bar{x}_{t}\right)-f^{\star}+\overbrace{f\left(\bar{x}_{T}\right)-\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T} \alpha_{t} f\left(\bar{x}_{t}\right)}^{:=\varepsilon_{T}} \\
& =\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T} \alpha_{t}\left(f\left(\bar{x}_{t}\right)-f^{\star}\right)+\varepsilon_{T} \\
& =\frac{1}{\alpha_{1: T}}[\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), \bar{x}_{t}-x^{\star}\right\rangle-\sum_{t=1}^{T} \overbrace{\alpha_{t} B_{f}\left(x^{\star}, \bar{x}_{t}\right)}^{:=B_{t}}]+\varepsilon_{T} \\
& =\frac{1}{\alpha_{1: T}}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), x_{t}-x^{\star}\right\rangle+\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), \bar{x}_{t}-x_{t}\right\rangle-B_{1: T}\right]+\varepsilon_{T} \\
& =\frac{1}{\alpha_{1: T}}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), x_{t}-x^{\star}\right\rangle-B_{1: T}\right]+\overbrace{\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), \bar{x}_{t}-x_{t}\right\rangle+\varepsilon_{T}}^{:=\tilde{\Delta}_{T}} \tag{28}
\end{align*}
$$

Before evaluating $\tilde{\Delta}_{T}$, we consider the term,

$$
\begin{align*}
\Delta_{T} & =\frac{1}{\alpha_{1: T}}\left[\sum_{t=2}^{T}\left\langle f^{\prime}\left(\bar{x}_{t}\right), \alpha_{1: t-1}\left(\bar{x}_{t-1}-\bar{x}_{t}\right)\right\rangle\right]+\varepsilon_{T} \\
& =\frac{1}{\alpha_{1: T}}\left[\sum_{t=2}^{T} \alpha_{1: t-1}\left(f\left(\bar{x}_{t-1}\right)-f\left(\bar{x}_{t}\right)-B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right)\right)\right]+\varepsilon_{T} \\
& =\frac{1}{\alpha_{1: T}} \sum_{t=2}^{T} \alpha_{1: t-1}\left(f\left(\bar{x}_{t-1}\right)-f\left(\bar{x}_{t}\right)\right)-\frac{1}{\alpha_{1: T}} \sum_{t=2}^{T} \alpha_{1: t-1} B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right)+\varepsilon_{T} \\
& =\underbrace{\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T} \alpha_{t} f\left(\bar{x}_{t}\right)-f\left(\bar{x}_{T}\right)+\varepsilon_{T}}_{:=0}-\frac{1}{\alpha_{1: T}} \sum_{t=2}^{T} \underbrace{\alpha_{1: t-1} B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right)}_{: \bar{B}_{t}^{f}} \tag{29}
\end{align*}
$$

Let us now evaluate $\tilde{\Delta}_{T}$. We have :

$$
\begin{align*}
\tilde{\Delta}_{T} & =\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), \bar{x}_{t}-x_{t}\right\rangle+\varepsilon_{T} \\
& \stackrel{211}{\frac{1}{\alpha_{1: T}}} \sum_{t=1}^{T}\left\langle f^{\prime}\left(\bar{x}_{t}\right), \alpha_{1: t-1}\left(\bar{x}_{t-1}-\bar{x}_{t}\right)+p_{t}\left(\tilde{x}_{t}-\bar{x}_{t}\right)\right\rangle+\varepsilon_{T} \\
& =\underbrace{\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T}\left\langle f^{\prime}\left(\bar{x}_{t}\right), \alpha_{1: t-1}\left(\bar{x}_{t-1}-\bar{x}_{t}\right)\right\rangle+\varepsilon_{T}}_{:=\Delta_{T}}+\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T} p_{t}\left\langle f^{\prime}\left(\bar{x}_{t}\right), \tilde{x}_{t}-\bar{x}_{t}\right\rangle  \tag{30}\\
& =\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T} p_{t}\left\langle f^{\prime}\left(\bar{x}_{t}\right), \tilde{x}_{t}-\bar{x}_{t}\right\rangle-\frac{1}{\alpha_{1: T}} \sum_{t=2}^{T} \bar{B}_{t}^{f} \\
& =\frac{1}{\alpha_{1: T}} \sum_{t=1}^{T} p_{t}\left(f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)-B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)\right)-\frac{1}{\alpha_{1: T}} \sum_{t=2}^{T} \bar{B}_{t}^{f}
\end{align*}
$$

The second last equation comes directly from Equation 29 Hence, finally we have:

$$
\begin{equation*}
f\left(\bar{x}_{T}\right)-f^{\star}=\frac{1}{\alpha_{1: T}}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), x_{t}-x^{\star}\right\rangle-B_{1: T}-\sum_{t=2}^{T} \bar{B}_{t}^{f}+\sum_{t=1}^{T} p_{t}\left(f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)-B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)\right)\right] \tag{31}
\end{equation*}
$$

The following variance bound is standard in the literature (e.g., Allen-Zhu 2017. Lemma 2.4). For completeness, we provide a proof using our assumptions and notation.
Lemma 10. Fix $t \geq 1$ and assume that 18 holds, and $g_{t}$ is given by 17). Further assume that for all $\zeta, F(\cdot, \zeta)$ is convex and L-smooth w.r.t. the 2 -norm $\|\cdot\|$ over $\mathbb{R}^{d}$ or otherwise satisfies (2) for all $x, y \in \mathcal{X}$. Then,

$$
\mathbb{E}\left[\left\|g_{t}-f^{\prime}\left(\bar{x}_{t}\right)\right\|^{2}\right] \leq \mathbb{E}\left[\left\|F^{\prime}\left(\bar{x}_{t}, \zeta_{t}\right)-F^{\prime}\left(\tilde{x}_{t}, \zeta_{t}\right)\right\|^{2}\right] \leq 2 L \mathbb{E}\left[B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)\right]
$$

Proof. By the smoothness assumption on $F(\cdot, \zeta)$, which implies (2), we have

$$
\begin{equation*}
\left\|F^{\prime}(x, \zeta)-F^{\prime}\left(x^{\prime}, \zeta\right)\right\|^{2} \leq 2 L\left(F(x, \zeta)-F\left(x^{\prime}, \zeta\right)-\left\langle F^{\prime}\left(x^{\prime}, \zeta\right), x-x^{\prime}\right\rangle\right) \tag{32}
\end{equation*}
$$

for all $x, x^{\prime} \in \mathcal{X}$. Now, thanks to $\mathbb{E}\left[\|U-\mathbb{E}[U]\|^{2}\right] \leq \mathbb{E}\left[\|U\|^{2}\right]$ which holds for any random vector $U$, and noticing that $\tilde{x}_{t}$ and $\bar{x}_{t}$ are determined by $\mathcal{H}_{t}$ by construction, we have

$$
\begin{align*}
& \mathbb{E}\left[\left\|g_{t}-f^{\prime}\left(\bar{x}_{t}\right)\right\|^{2} \mid \mathcal{H}_{t}\right]=\mathbb{E}\left[\left\|F^{\prime}\left(\bar{x}_{t}, \zeta_{t}\right)-f^{\prime}\left(\bar{x}_{t}\right)-\left(F^{\prime}\left(\tilde{x}_{t}, \zeta_{t}\right)-f^{\prime}\left(\tilde{x}_{t}\right)\right)\right\|^{2} \mid \mathcal{H}_{t}\right] \\
& \quad \leq \mathbb{E}\left[\left\|F^{\prime}\left(\bar{x}_{t}, \zeta_{t}\right)-F^{\prime}\left(\tilde{x}_{t}, \zeta_{t}\right)\right\|^{2} \mid \mathcal{H}_{t}\right] \\
& \quad \leq 2 L \mathbb{E}\left[F\left(\tilde{x}_{t}, \zeta_{t}\right)-F\left(\bar{x}_{t}, \zeta_{t}\right)-\left\langle F^{\prime}\left(\bar{x}_{t}, \zeta_{t}\right), \tilde{x}_{t}-\bar{x}_{t}\right\rangle \mid \mathcal{H}_{t}\right]  \tag{by32}\\
& \quad=2 L\left[f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)-\left\langle f^{\prime}\left(\bar{x}_{t}\right), \tilde{x}_{t}-\bar{x}_{t}\right\rangle\right] .
\end{align*}
$$

Taking the expectation of both sides finishes the proof.
Proof of Theorem 8 Note that $B_{f}\left(\tilde{x}_{1}, \bar{x}_{1}\right)=0$. Also since, $\phi=0, \ell(x)=f(x)$ for all $x$, hence we will be using $f$ instead of $\ell$ in the proof. Let $s(t)$ represents the epoch containing iteration $t$. From Lemma 7 , we have :

$$
\begin{equation*}
f\left(\bar{x}_{T}\right)-f^{\star}=\frac{1}{\alpha_{1: T}}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), x_{t}-x^{\star}\right\rangle-B_{1: T}-\sum_{t=2}^{T} \bar{B}_{t}^{f}+\sum_{t=1}^{T} p_{t}\left(f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)-B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)\right)\right] . \tag{33}
\end{equation*}
$$

Now we have:

$$
\frac{1}{\alpha_{1: T}}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right), x_{t}-x^{\star}\right\rangle\right]=\frac{1}{\alpha_{1: T}}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} f^{\prime}\left(\bar{x}_{t}\right)-\alpha_{t} g_{t}+\alpha_{t} g_{t}, x_{t}-x^{\star}\right\rangle\right]=\frac{1}{\alpha_{1: T}}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} g_{t}, x_{t}-x^{\star}\right\rangle+\delta_{1: T}\right]
$$

where $\delta_{t}=\alpha_{t}\left\langle f^{\prime}\left(\bar{x}_{t}\right)-g_{t}, x_{t}-x^{\star}\right\rangle$. By 18$]$, we have $\mathbb{E}\left[\delta_{t}\right]=0$ for all $t \in[T]$. By Theorem 17 in the appendix,

$$
\frac{1}{\alpha_{1: T}} \mathbb{E}\left[\sum_{t=1}^{T}\left\langle\alpha_{t} g_{t}, x_{t}-x^{\star}\right\rangle\right] \leq \mathcal{R}_{T}\left(x^{\star}\right)=\frac{\eta_{T}}{2}\left\|x^{\star}\right\|_{2}^{2}+\sum_{t=1}^{T} \frac{\alpha_{t}^{2}}{2 \eta_{t}} \mathbb{E}\left[\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2}\right]
$$

Putting back in (33), and using the fact that due to convexity of $f, B_{1: T} \geq 0$, we have:

$$
\begin{equation*}
\mathbb{E}\left[f\left(\bar{x}_{T}\right)\right]-f\left(x^{\star}\right) \leq \frac{1}{\alpha_{1: T}} \mathbb{E}\left[\frac{\eta_{T}}{2}\left\|x^{\star}\right\|_{2}^{2}+\sum_{t=1}^{T} \frac{\alpha_{t}^{2}}{2 \eta_{t}}\left\|g_{t}-\tilde{g}_{t}\right\|_{2}^{2}-\bar{B}_{2: T}^{f}+\sum_{t=1}^{T} p_{t}\left(f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)-B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)\right)\right] \tag{34}
\end{equation*}
$$

Next, using $\tilde{g}_{t}=g_{t-1}, t>1$, and applying Lemma 10, we have

$$
\begin{aligned}
\sum_{t=2}^{T} \frac{\alpha_{t}^{2}}{2 \eta_{t}} \mathbb{E}\left[\left\|g_{t}-\tilde{g}_{t}\right\|^{2}\right] & =\sum_{t=2}^{T} \frac{\alpha_{t}^{2}}{2 \eta_{t}} \mathbb{E}\left[\left\|g_{t}-f^{\prime}\left(\bar{x}_{t}\right)+f^{\prime}\left(\bar{x}_{t-1}\right)-g_{t-1}+f^{\prime}\left(\bar{x}_{t}\right)-f^{\prime}\left(\bar{x}_{t-1}\right)\right\|^{2}\right] \\
& \leq \sum_{t=2}^{T} \frac{3 \alpha_{t}^{2}}{2 \eta_{t}} \mathbb{E}\left[\left\|g_{t}-f^{\prime}\left(\bar{x}_{t}\right)\right\|^{2}+\left\|f^{\prime}\left(\bar{x}_{t-1}\right)-g_{t-1}\right\|^{2}+\left\|f^{\prime}\left(\bar{x}_{t}\right)-f^{\prime}\left(\bar{x}_{t-1}\right)\right\|^{2}\right] \\
& \leq \sum_{t=2}^{T} \frac{3 \alpha_{t}^{2}}{2 \eta_{t}} \mathbb{E}\left[2 L B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)+2 L B_{f}\left(\tilde{x}_{t-1}, \bar{x}_{t-1}\right)+2 L B_{f}\left(\bar{x}_{t-1}, \bar{x}_{t}\right)\right] \\
& \leq \sum_{t=1}^{T} \frac{3 L\left(\alpha_{t}^{2}+\alpha_{t+1}^{2}\right)}{\eta_{t}} \mathbb{E}\left[B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)\right]+\sum_{t=2}^{T} \frac{12 L}{\eta_{t}} \mathbb{E}\left[\bar{B}_{t}^{f}\right]
\end{aligned}
$$

where the second step uses Jensen's inequality and the convexity of $\|\cdot\|^{2}$, the third step follows by the smoothness assumption on $f$ and Lemma 10, and the fourth step follows by $\eta_{t+1} \geq \eta_{t}$ and $\frac{\alpha_{t}^{2}}{\alpha_{1: t-1}} \leq 4$. Putting back into (34) with $\tilde{g}_{1}=0$,

$$
\begin{align*}
\mathbb{E}\left[f\left(\bar{x}_{T}\right)\right]-f\left(x^{\star}\right) \leq & \frac{1}{\alpha_{1: T}} \mathbb{E}[\frac{\eta_{T}}{2}\left\|x^{\star}\right\|_{2}^{2}+\frac{\alpha_{1}^{2}}{2 \eta_{1}}\left\|g_{1}\right\|^{2}+\underbrace{\sum_{t=1}^{T} p_{t}\left(f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)\right)}_{\Gamma_{T}}] \\
& +\sum_{t=1}^{T}\left(\frac{3 L\left(\alpha_{t}^{2}+\alpha_{t+1}^{2}\right)}{\eta_{t}}-p_{t}\right) \mathbb{E}\left[B_{f}\left(\tilde{x}_{t}, \bar{x}_{t}\right)\right]+\sum_{t=2}^{T}\left(\frac{12 L}{\eta_{t}}-1\right) \mathbb{E}\left[\bar{B}_{t}^{f}\right] . \tag{35}
\end{align*}
$$

Noticing that $p_{t} \geq \frac{15 L \alpha_{t}^{2}}{\eta_{t}} \geq \frac{3 L\left(\alpha_{t}^{2}+\alpha_{t+1}^{2}\right)}{\eta_{t}}$ and $\eta_{t} \geq 12 L$, the last two terms in (35) vanish.
In the rest of the proof, we will bound the term $\Gamma_{T}$ and use induction to get the final convergence rate. Let us denote $\mathbb{E}\left[f\left(\bar{x}_{t}\right)-f^{\star}\right]$ with $D_{t}$ and $\mathbb{E}\left[f\left(\tilde{x}_{t}\right)-f^{\star}\right]$ with $\tilde{D}_{s(t)}$. Let us also represent the snapshot point for epoch $s$ by $\tilde{x}^{s}$. Hence, $\tilde{D}(s)=\mathbb{E}\left[f\left(\tilde{x}_{s}\right)\right]-f^{\star}$. We also assume that $T_{1: S}<T \leq T_{1: S+1}$. Then

$$
\begin{align*}
\sum_{t=1}^{T} p_{t}\left(f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)\right) & =\sum_{t=1}^{T} p_{t}\left(\tilde{D}_{s(t)}-D_{t}\right) \\
& \leq p_{1} \tilde{D}(1)+\sum_{s=2}^{S+1} \tilde{D}(s)\left(\sum_{t=T_{1: s-1}+1}^{T_{1: s}} p_{t}\right)-\sum_{s=1}^{S}\left(\sum_{t=T_{1: s-1}+1}^{T_{1: s}} p_{t} D_{t}\right) \tag{36}
\end{align*}
$$

From the definition of $\tilde{x}_{s}$, we can apply Jensen's inequality to get

$$
\begin{equation*}
\sum_{t=1}^{T} p_{t}\left(f\left(\tilde{x}_{t}\right)-f\left(\bar{x}_{t}\right)\right) \leq p_{1} \tilde{D}(1)+\sum_{s=1}^{S}\left(\sum_{t=T_{1: s-1}+1}^{T_{1: s}} p_{t} D_{t}\right) \underbrace{\left(\frac{\sum_{t=T_{1: s}+1}^{T_{1: s+1}} p_{t}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} p_{t}}-1\right)}_{:=\Theta_{s}} \tag{37}
\end{equation*}
$$

Let us assume that for $p_{t}=\frac{\alpha_{t}^{2}}{\gamma_{t} T_{s(t)}} \forall t \in\left[T_{1: s-1}+1, T_{1: s}\right]$ where $\alpha_{t}=t$ and $\gamma_{t}$ is an increasing sequence of positive numbers. We rewrite the term $\Theta_{s}$.

$$
\Theta_{s}=\left(\frac{\sum_{t=T_{1: s}+1}^{T_{1: s+1}} p_{t}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} p_{t}}-1\right) \leq\left(\frac{T_{s}}{T_{s+1}} \frac{\sum_{t=T_{1: s}+1}^{T_{1: s+1}} t^{2} / \gamma_{t}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} t^{2} / \gamma_{t}}-1\right) \leq\left(\frac{T_{s}}{T_{s+1}} \frac{\left(\gamma_{T_{1: s}}\right)^{-1} \sum_{t=T_{1: s}+1}^{T_{1: s+1}} t^{2}}{\left(\gamma_{T_{1: s}}\right)^{-1} \sum_{t=T_{1: s-1}+1}^{T_{1: s}} t^{2}}-1\right)
$$

We let $s^{\prime}$ be the smallest index for which $T_{s}=\tau$ for all $s>s^{\prime}$. Hence, for $s>s^{\prime}$ we have following bound for $\Theta_{s}$ :

$$
\begin{aligned}
\Theta_{s} & \leq\left(\frac{T_{s}}{T_{s+1}} \frac{\sum_{t=T_{1: s}+1}^{T_{1: s+1}} t^{2}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} t^{2}}-1\right)=\left(\frac{\sum_{t=T_{1: s}+1}^{T_{1: s+1}} t^{2}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} t^{2}}-1\right)=\left(\frac{\sum_{t=T_{1: s}+1}^{T_{1: s}+\tau} t^{2}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}+\tau} t^{2}}-1\right) \\
& =\left(\frac{\sum_{t=T_{1: s-1}+1}^{T_{1: s-1}+\tau}(t+\tau)^{2}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s-1}+\tau} t^{2}}-1\right)=\left(\frac{\sum_{t=T_{1: s-1}+1}^{T_{1: s-1}+\tau}(t+\tau)^{2}-t^{2}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s-1}+\tau} t^{2}}\right)=\left(\frac{\sum_{t=T_{1: s-1}+1}^{T_{1: s-1}+\tau} \tau(2 t+\tau)}{\sum_{t=T_{1: s-1}+1}^{T_{1: s-1}+\tau} t^{2}}\right) \\
& \leq \frac{\tau^{2}\left(2 T_{1: s-1}+3 \tau\right)}{\left(T_{1: s-1}+1\right)^{2} \tau} \leq \frac{\tau\left(2 T_{1: s-1}+3\left(T_{1: s-1}+1\right)\right)}{\left(T_{1: s-1}+1\right)^{2}} \leq 5 \frac{\tau}{T_{1: s-1}+1}=5 \frac{T_{s}}{T_{1: s-1}+1},
\end{aligned}
$$

using in the last step the fact that $s^{\prime}<s$ implies $\tau=T_{s} \leq T_{1: s-1}+1$ (which follows because if $T_{s-1}=2^{s-2}$, then $T_{1: s-1}+1=2^{s-1} \geq T_{s}$, and is trivial if otherwise $T_{s-1}=\tau$ ). Now let us consider the case when $s \leq s^{\prime}$. In that case, $T_{s+1} \leq 2^{s}=2 T_{s}$, which can be used to show $\frac{\sum_{t=T_{1: s}+1}^{T_{1: s}+1} t^{2}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} t^{2}} \leq 2\left(\frac{T_{1: s+1}}{T_{1: s-1}+1}\right)^{2} \leq 2\left(\frac{T_{1: s}+2 T_{s}}{T_{1: s-1}+1}\right)^{2} \leq 2\left(\frac{2^{s+1}-1}{2^{s-1}}\right)^{2} \leq 32$, so

$$
\Theta_{s} \leq\left(\frac{T_{s}}{T_{s+1}} \frac{\sum_{t=T_{1: s}+1}^{T_{1: s}} t^{2}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} t^{2}}-1\right) \leq\left(\frac{\sum_{t=T_{1: s}+1}^{T_{1: s}} t^{2}}{\sum_{t=T_{1: s-1}+1}^{T_{1: s}} t^{2}}-1\right) \leq 31
$$

Hence,

$$
\begin{align*}
D_{T} & \leq \frac{1}{\alpha_{1: T}}\left[\frac{\eta_{T}}{2}\left\|x^{\star}\right\|^{2}+\frac{1}{2 \eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+p_{1} \tilde{D}(1)+\sum_{s=1}^{S} \Theta_{s} \sum_{t=T_{1: s-1}+1}^{T_{1: s}} \frac{\alpha_{t}^{2}}{\gamma_{t} T_{s}} D_{t}\right] \\
& \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\sum_{s=1}^{S} \Theta_{s} \sum_{t=T_{1: s-1}+1}^{T_{1: s}} \frac{2 t^{2}}{\gamma_{t} T_{s}} D_{t}\right] \tag{38}
\end{align*}
$$

In the above equation, we can choose $\gamma_{t}=124 \log (2 t)$ then we have:

$$
\begin{equation*}
D_{T} \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\hat{\eta}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\sum_{s=1}^{S} \Theta_{s} \sum_{t=T_{1: s-1}+1}^{T_{1: s}} \frac{2 t^{2}}{124 \log (2 t) T_{s}} D_{t}\right] \tag{39}
\end{equation*}
$$

Now, it is important to remember that $p_{t} \geq \frac{15 L \alpha_{t}^{2}}{\eta_{t}}$, which is satisfied if $\eta_{t}=1860 L T_{s(t)} \log (2 t)$. We now use 39) to prove the following statement by induction:

$$
D_{T} \leq \frac{T_{s(T)} \log (2 T)}{T^{2}}\left[3720 L\left\|x^{\star}\right\|^{2}+\frac{2}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+4 p_{1} \tilde{D}(1)\right]=\frac{C T_{s(T)} \log (2 T)}{T^{2}}
$$

where $C=3720 L\left\|x^{\star}\right\|^{2}+\frac{2}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+4 p_{1} \tilde{D}(1)$.
For $T=1$, the bound is satisfied trivially, since $C \geq 2 D_{1}$ by 35 . Next, let $T>1$, and assume the induction hypothesis holds for all $t \leq T-1$. Then, we have:

$$
D_{T} \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\sum_{s=1}^{S} \Theta_{s} \sum_{t=T_{1: s-1}+1}^{T_{1: s}} \frac{2 t^{2}}{124 \log (2 t) T_{s}} D_{t}\right]
$$

$$
\begin{aligned}
& \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\sum_{s=1}^{S} \Theta_{s} \sum_{t=T_{1: s-1}+1}^{T_{1: s}} \frac{2}{124} C\right] \\
& =\frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\sum_{s=1}^{S} \Theta_{s} T_{s} \frac{2}{124} C\right]
\end{aligned}
$$

where the second step uses the induction hypothesis on $D_{t}$ for $t<T$. Then, on the one hand, if $S \leq s^{\prime}$, we have:

$$
\begin{aligned}
D_{T} & \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+31\left(\log \left(T_{S}\right)+1\right) \frac{2 T_{S}}{124} C\right] \\
& =\frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\log (2 T) \frac{T_{S}}{2} C\right]
\end{aligned}
$$

where in the first step we use $T_{s} \leq T_{S}$, the earlier bound $\Theta_{s} \leq 31$ for $s \leq s^{\prime}$, and $S=\log _{2}\left(2^{S-1}\right)+1=\log _{2}\left(T_{S}\right)+1$, and in the second step we use $1=\log _{2}(2)$. On the other hand, if $S>s^{\prime}$ :

$$
\begin{aligned}
D_{T} & \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\sum_{s=1}^{s^{\prime}} \Theta_{s} \frac{2 T_{S}}{124} C+\sum_{s=s^{\prime}+1}^{S} \Theta_{s} \frac{2 T_{S}}{124} C\right] \\
& \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+31(\log (\tau)+1) \frac{2 T_{S}}{124} C+\sum_{s=s^{\prime}+1}^{S} 5 \frac{\tau}{\left(s-s^{\prime}\right) \tau} \frac{2 T_{S}}{124} C\right] \\
& \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+31 \log (2 \tau) \frac{2 T_{S}}{124} C+5 \log \left(S-s^{\prime}+1\right) \frac{2 T_{S}}{124} C\right] \\
& \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+31 \log (2 \tau) \frac{2 T_{S}}{124} C+31 \log \left(S-s^{\prime}\right) \frac{2 T_{S}}{124} C\right] \\
& \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\log (2 T) \frac{T_{S}}{2} C\right]
\end{aligned}
$$

In the derivations above, the second step follows because by the definition of $s^{\prime}, s^{\prime} \leq \log (\tau)+1$ and also $T_{1: s^{\prime}}+1=2^{s^{\prime}} \geq$ $T_{s^{\prime}+1}=\tau$. The third step uses $1=\log _{2}(2)$ and $\sum_{s=s^{\prime}+1}^{S} 1 /\left(s-s^{\prime}\right)=\sum_{j=1}^{S-s^{\prime}} 1 / j \leq \log \left(S-s^{\prime}+1\right)$. The fourth step uses $\log (j+1) \leq 6 \log (j)$ for any $j>1$. The fifth step uses $\left(S-s^{\prime}\right) \tau \leq T_{1: S}<T$.

Hence, in both cases, we have

$$
\begin{aligned}
D_{T} & \leq \frac{1}{T^{2}}\left[\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)+\log (2 T) \frac{T_{S}}{2} C\right] \\
& \leq \frac{1}{T^{2}}[\underbrace{\eta_{T}\left\|x^{\star}\right\|^{2}+\frac{1}{\eta_{1}}\left\|f^{\prime}\left(x_{1}\right)\right\|^{2}+2 p_{1} \tilde{D}(1)}_{\frac{\leq C T_{s(T)} \log (2 T)}{2}}+\frac{C T_{s(T)} \log (2 T)}{2}] \\
& \leq \frac{C T_{s(T)} \log (2 T)}{T^{2}},
\end{aligned}
$$

using that $T_{S} \leq T_{S+1}=T_{s(T)}$. This concludes the proof.

## E. Regret bounds for online linear optimization

In this section, we provide the conditions and regret-bound $\mathcal{R}_{T}$ for vanilla AO-FTRL, which is used by Theorems 3 and 5 , as well as the SVRG results. The analysis is based on Joulani et al. (2017; 2020).
Theorem 17. Let $\phi: \mathcal{X} \rightarrow \mathbb{R}$ be a convex function. For $t \in[T]$, let $r_{t}: \mathcal{X} \rightarrow \mathbb{R}, \alpha_{t}>0, g_{t}, \tilde{g}_{t} \in \mathbb{R}^{d}, x_{t} \in \mathcal{X}$ be such that the AO-FTRL update (4) is well-defined and $x_{t}$ is given by (4) for all $t \in[T]$. Suppose that for all $t \in[T]$, $r_{t-1}$ is convex
and the objective in the AO-FTRL update (4) has finite value at the optimum $x_{t}$. Then, for any $x \in \mathcal{X}$,

$$
\begin{align*}
\sum_{t=1}^{T} \alpha_{t}\left(\left\langle g_{t}, x_{t}-x\right\rangle+\phi\left(x_{t}\right)-\phi(x)\right) \leq & \sum_{t=1}^{T}\left(r_{t-1}(x)-r_{t-1}\left(x_{t}\right)-B_{\alpha_{1: t} \phi+r_{0: t-1}}\left(x_{t+1}, x_{t}\right)\right) \\
& +\sum_{t=1}^{T} \alpha_{t}\left\langle g_{t}-\tilde{g}_{t}, x_{t}-x_{t+1}\right\rangle \tag{40}
\end{align*}
$$

If, in addition, for all $t \in[T], B_{\alpha_{1: t} \phi+r_{0: t-1}}\left(x_{t+1}, x_{t}\right) \geq \frac{1}{2}\|\cdot\|_{(t)}^{2}$ for some norm $\|\cdot\|_{(t)}$, then

$$
\begin{equation*}
\sum_{t=1}^{T} \alpha_{t}\left(\left\langle g_{t}, x_{t}-x\right\rangle+\phi\left(x_{t}\right)-\phi(x)\right) \leq \sum_{t=1}^{T}\left(r_{t-1}(x)-r_{t-1}\left(x_{t}\right)\right)+\sum_{t=1}^{T} \frac{\alpha_{t}^{2}}{2}\left\|g_{t}-\tilde{g}_{t}\right\|_{(t) *}^{2} \tag{41}
\end{equation*}
$$

Proof. The assumption that $\phi$ and $r_{t}$ are real-valued and defined on $\mathcal{X}$ ensures that they are proper, which, together with convexity ensures that $\alpha_{1: t} \phi+r_{0: t-1}$ is directionally differentiable Bauschke and Combettes, 2011, Prop. 17.2). Together with the assumption that the AO-FTRL objective in (4) is finite-valued, we guarantee Assumption 1 of Joulani et al. (2020), while their Assumption 5 is satisfied given that the combined linear-composite function $\alpha_{t}\left(\left\langle g_{t}, \cdot\right\rangle+\phi\right)$ is convex. The first bound (40) then follows from the intermediate bound C. 1 in the proof of Theorem 6 of Joulani et al. (2020), using $x^{*} \leftarrow x, g_{t} \leftarrow \alpha_{t} g_{t}, \tilde{g}_{T+1} \leftarrow 0, p_{t} \leftarrow 0, t \in[T], \tilde{q}_{t} \leftarrow r_{t}+\alpha_{t+1} \phi, t \in\{0\} \cup[T-1]$, and $\tilde{q}_{T} \leftarrow 0$. The second bound (41) follows from the statement of Theorem 6 of Joulani et al. (2020), using using $x^{*} \leftarrow x, p_{t} \leftarrow 0, t \in[T]$, and $\tilde{q}_{t} \leftarrow r_{t}+\alpha_{t+1} \phi, t \in\{0\} \cup[T-1]$, noting that Assumption 8 of Joulani et al. (2020) is the extra condition we have assumed in the second part of the theorem.

[^1]:    ${ }^{1}$ We do not require $\mathcal{X}$ to be closed or compact, which are normally assumed to ensure $x^{\star}$ exists.

[^2]:    ${ }^{2}$ Extensions when $f$ is non-differentiable at boundary points are straightforward.
    ${ }^{3}$ Assuming only that (ii) holds for all $x, y \in \mathcal{X}$ does not imply (ii) or (2) in general (even for $x, y \in \mathcal{X}$ ). E.g., $f^{\prime}(x)$ can grow arbitrarily in the directions orthogonal to $\mathcal{X}$ while (i) holds.

[^3]:    ${ }^{4}$ Note that instead of using a norm, here we set $\|\cdot\|_{(t)}$ in Theorem 3 to be zero. While this is not a valid choice, an inspection of the proof of the theorem verifies that the theorem still holds in this case if the dual norm is set to zero and $\sigma_{t}=0$ for all $t$.
