Abstract

This supplementary material contains all proofs and technical details omitted from the main text, along with ancillary comments, discussion about related work, and extra experimental results.

1. Proof of Theorem 1

The following sequence of lemmas are of preliminary importance. The first one needs extra variance conditions on the process $X$ generating the context vectors.

We find it convenient to introduce the node counterpart to $\text{TCB}_{i,t-1}(x)$, and the cluster counterpart to $\overline{\text{TCB}}_{j,t-1}$. Given round $t$, node $i \in V$, and cluster index $j \in \{1, \ldots, m_t\}$, we let

$$\text{TCB}_{i,t-1}(x) = \sqrt{x^\top M_{i,t-1}^{-1} x} \left( \frac{\sigma}{\sqrt{2 \log \frac{|M_{i,t-1}|}{\delta^2}} + 1} \right)$$

$$\overline{\text{TCB}}_{j,t-1} = \frac{\sigma}{\sqrt{2d \log t + 2 \log \frac{2}{\delta}} + 1} \frac{1}{\lambda_{\text{max}}(T_{j,t-1}, \delta/(2^{m+1}d))},$$

being

$$T_{j,t-1} = \sum_{s \in V_{i,t}} T_{i,t-1} = | \{ s \leq t - 1 : i_s \in V_{i,t} \}|,$$

i.e., the number of past rounds where a node lying in cluster $V_{i,t}$ was served. From a notational standpoint, notice the difference\footnote{Also observe that $2\sigma$ has been replaced by $2^{m+1}d$ inside the log’s.} between $\text{TCB}_{i,t-1}$ and $\overline{\text{TCB}}_{j,t-1}(x)$, both referring to a single node $i \in V$, and $\overline{\text{TCB}}_{j,t-1}$ and $\text{TCB}_{j,t-1}(x)$ which refer to an aggregation (cluster) of nodes $j$ among the available ones at time $t$.

Lemma 1. Let, at each round $t$, context vectors $C_{i_t} = \{x_{t,1}, \ldots, x_{t,c_t}\}$ being generated i.i.d. (conditioned on $c_t$, $x_{i,t}$ and all past indices $i_1, \ldots, i_{t-1}$, rewards $a_{1,t}, \ldots, a_{t-1}$, and sets $C_{i_1}, \ldots, C_{i_{t-1}}$) from a random process $X$ such that $|X| = 1$, $\mathbb{E}[XX^\top]$ is full rank, with minimal eigenvalue $\lambda > 0$. Let also, for any fixed unit vector $z \in \mathbb{R}^{d}$, the random variable $(z^\top X)^2$ be (conditionally) sub-Gaussian with variance parameter $^2$

$$\nu^2 = \mathbb{V}_t \left[ (z^\top X)^2 \mid c_t \right] \leq \frac{\lambda^2}{8 \log(4 \epsilon t)} \forall t.$$  

Then

$$\text{TCB}_{i,t}(x) \leq \overline{\text{TCB}}_{i,t}$$

holds with probability at least $1 - \delta/2$, uniformly over $i \in V$, $t = 0, 1, 2, \ldots$, and $x \in \mathbb{R}^{d}$ such that $|x| = 1$.

Proof. Fix node $i \in V$ and round $t$. By the very way the algorithm in Figure 1 is defined, we have

$$M_{i,t} = I + \sum_{s \leq t : i_s = i} \bar{x}_s \bar{x}_s^\top = I + S_{i,t}.$$

First, notice that by standard arguments (e.g., (Dekel et al., 2010)) we have

$$\log |M_{i,t}| \leq d \log(1 + T_{i,t}/d) \leq d \log(1 + t).$$

Moreover, denoting by $\lambda_{\max}(\cdot)$ and $\lambda_{\min}(\cdot)$ the maximal and the minimal eigenvalue of the matrix at argument we

\footnote{Random variable $(z^\top X)^2$ is conditionally sub-Gaussian with variance parameter $\sigma^2 > 0$ when $\mathbb{E}_t[\exp(\gamma (z^\top X)^2)] c_t \leq \exp(\sigma^2 \gamma^2/2)$ for all $\gamma \in \mathbb{R}$. The sub-Gaussian assumption can be removed here at the cost of assuming the conditional variance of $(z^\top X)^2$ scales with $c_t$ like $\frac{\lambda^2}{c_t}$, instead of $\frac{\lambda^2}{\log(c_t)}$.}
have that, for any fixed unit norm $x \in \mathbb{R}^d$,
\[
x^\top M_{i,t}^{-1} x \leq \lambda_{\max}(M_{i,t}^{-1}) = \frac{1}{1 + \lambda_{\min}(S_{i,t})}.
\]
Hence, we want to show with probability at least $1 - \delta/(2n)$ such that
\[
\lambda_{\min}(S_{i,t}) \geq \lambda T_{i,t}/4 - 8 \log \left( \frac{T_{i,t} + 3}{\delta/(2nd)} \right) - 2 \sqrt{T_{i,t} \log \left( \frac{T_{i,t} + 3}{\delta/(2nd)} \right)}
\]
holds for any fixed node $i$. To this end, fix a unit norm vector $z \in \mathbb{R}^d$, a round $s \leq t$, and consider the variable
\[
V_s = z^\top (\bar{x}_s \bar{x}_s^\top - E_s[\bar{x}_s \bar{x}_s^\top | c_s]) z
= (z^\top \bar{x}_s)^2 - E_s[(z^\top \bar{x}_s)^2 | c_s].
\]
The sequence $V_1, V_2, \ldots, V_{T_{i,t}}$ is a martingale difference sequence, with optional skipping, where $T_{i,t}$ is a stopping time. Moreover, the following claim holds.

Claim 1. Under the assumption of this lemma,
\[
E_s[(z^\top \bar{x}_s)^2 | c_s] \geq \lambda/4.
\]

Proof of claim. Let $^4$ in round $s$ the context vectors be $C_{i,s} = \{x_1, \ldots, x_s, c_s\}$, and consider the corresponding i.i.d. random variables $Z_i = (z^\top x_i)^2 - E_s[(z^\top x_i)^2 | c_s]$, $i = 1, \ldots, c_s$. Since by assumption these variables are (zero-mean) sub-Gaussian, we have that (see, e.g., (Massart, 2007)(Ch.2))
\[
\mathbb{P}_s(Z_i < -a | c_t) \leq \mathbb{P}_s(|Z_i| > a | c_t) \leq 2e^{-a^2/2}\delta^2.
\]
holds for any $i$, where $\mathbb{P}_s(\cdot)$ is the shorthand for the conditional probability
\[
\mathbb{P}(\cdot | (i_1, C_{i_1}, a_1), \ldots, (i_{s-1}, C_{i_{s-1}}, a_{s-1}), i_s).
\]
The above implies
\[
\mathbb{P}_s \left( \min_{i=1, \ldots, c_s} (z^\top x_{i,s})^2 \geq \lambda - a | c_t \right) \geq \left( 1 - 2e^{-a^2/2}\delta^2 \right)^{c_s}.
\]
Therefore
\[
E_s[(z^\top \bar{x}_s)^2 | c_s] \geq E_s \left[ \min_{i=1, \ldots, c_s} (z^\top x_{i,s})^2 | c_s \right] \geq (\lambda - a) \left( 1 - 2e^{-a^2/2}\delta^2 \right)^{c_s}.
\]
Since this holds for all $a \in \mathbb{R}$, we set $a = \sqrt{2\nu^2 \log(4c_s)}$ to get $\left( 1 - 2e^{-a^2/2}\delta^2 \right)^{c_s} = (1 - \frac{a}{\nu^2})^{c_s} \geq 1/2$ (because $c_s \geq 1$), and $\lambda - a \geq \lambda/2$ (because of the assumption on $\nu^2$). Putting together concludes the proof of the claim. \hfill \Box

We are now in a position to apply a Freedman-like inequality for matrix martingales due to (Oliveira, 2010; Tropp, 2011) to the (matrix) martingale difference sequence
\[
E_1[\bar{x}_1 \bar{x}_1^\top | c_1] - \bar{x}_1 \bar{x}_1^\top, E_2[\bar{x}_2 \bar{x}_2^\top | c_2] - \bar{x}_2 \bar{x}_2^\top, \ldots
\]
with optional skipping. Setting for brevity $X_s = \bar{x}_s \bar{x}_s^\top$, and
\[
W_t = \sum_{s \leq t : i_s = i} (E_s[X_s^2 | c_s] - E_s^2[X_s | c_s])
\]
Theorem 1.2 in (Tropp, 2011) implies
\[
\mathbb{P} \left( \exists t : \lambda_{\min}(S_{i,t}) \leq T_{i,t} \lambda_{\min}(E_1[X_1 | c_1]) - a, ||W_t|| \leq \sigma^2 \right) \leq d e^{-a^2/\delta^2}.
\]
where $||W_t||$ denotes the operator norm of matrix $W_t$.

We apply Claim 1, so that $\lambda_{\min}(E_1[X_1 | c_1]) \geq \lambda/4$, and proceed as in, e.g., (Cesa-Bianchi & Gentile, 2008). We set for brevity $A(x, \delta) = 2 \log (2 + 1)/(2\delta)$, and $f(A, r) = 2A \sqrt{A}$. We can write
\[
\mathbb{P} \left( \exists t : \lambda_{\min}(S_{i,t}) \leq \lambda_{\min}T_{i,t}/4 - f(A(||W_t||, \delta), ||W_t||) \right)
\leq \sum_{r=0}^{\infty} \mathbb{P} \left( \exists t : \lambda_{\min}(S_{i,t}) \leq \lambda_{\min}T_{i,t}/4 - f(A(r, \delta), r), ||W_t|| = r \right)
\leq \sum_{r=0}^{\infty} \mathbb{P} \left( \exists t : \lambda_{\min}(S_{i,t}) \leq \lambda_{\min}T_{i,t}/4 - f(A(r, \delta), r), ||W_t|| \leq r + 1 \right)
\leq d \sum_{r=0}^{\infty} e^{-r^2 A(r, \delta)/2} e^{-r^2 f(A(r, \delta), r)/2} f(A(r, \delta), r),
\]
the last inequality deriving from (2). Because $f(A, r)$ satisfies $f^2(A, r) \geq Ar + A + \frac{2}{3} f(A, r) A$, we have that the exponent in the last exponential is at least $A(r, \delta)/2$, implying
\[
\sum_{r=0}^{\infty} e^{-A(r, \delta)/2} = \sum_{r=0}^{\infty} \frac{\delta}{(r + 1)(r + 3)} < \delta
\]
which, in turn, yields
\[
\mathbb{P} \left( \exists t : \lambda_{\min}(S_{i,t}) \leq T_{i,t} \lambda_{\min}A/4 - f(A(||W_t||, \delta/d), ||W_t||) \right)
\leq \delta.
\]
Finally, observe that 
\[ ||W_i|| \leq \sum_{s \leq t: i_s = i} ||E_s[X_s^2 | c_s]|| \]
\[ = \sum_{s \leq t: i_s = i} ||E_s[X_s | c_s]|| \]
\[ \leq \sum_{s \leq t: i_s = i} E_s[||X_s | c_s||] \]
\[ \leq T_{i,t}. \]

Therefore we conclude
\[
\mathbb{P}(\forall t: \lambda_{\min}(S_{i,t}) \geq \lambda_{\min}(T_{i,t})/4 - f(A(T_{i,t}, \delta/d), T_{i,t})) \\
\geq 1 - \delta.
\]

Stratifying over \( i \in V \), replacing \( \delta \) by \( \delta/(2n) \) in the last inequality, and overapproximating proves the lemma. \( \square \)

**Lemma 2.** Under the same assumptions as in Lemma 1, we have
\[ ||u_i - w_{i,t}|| \leq \bar{TCB}_{i,t} \]
holds with probability at least \( 1 - \delta \), uniformly over \( i \in V \), and \( t = 0, 1, 2, \ldots \).

**Proof.** From (Abbasi-Yadkori et al., 2011) it follows that
\[ ||u_i^T x - w_{i,t}^T x|| \leq TCB_{i,t}(x) \]
holds with probability at least \( 1 - \delta/2 \), uniformly over \( i \in V, t = 0, 1, 2, \ldots \) and \( x \in \mathbb{R}^d \). Hence,
\[ ||u_i - w_{i,t}|| \leq \max_{x \in \mathbb{R}^d: ||x|| = 1} ||u_i^T x - w_{i,t}^T x|| \]
\[ \leq \max_{x \in \mathbb{R}^d: ||x|| = 1} TCB_{i,t}(x) \]
\[ \leq \bar{TCB}_{i,t}, \]
the last inequality holding with probability \( \geq 1 - \delta/2 \) by Lemma 1. This concludes the proof. \( \square \)

**Lemma 3.** Under the same assumptions as in Lemma 1:

1. If \( ||u_i - u_j|| \geq \gamma \) and \( \bar{TCB}_{i,t} + \bar{TCB}_{j,t} < \gamma/2 \) then
\[ ||w_{i,t} - w_{j,t}|| > \bar{TCB}_{i,t} + \bar{TCB}_{j,t} \]
holds with probability at least \( 1 - \delta \), uniformly over \( i, j \in V \) and \( t = 0, 1, 2, \ldots \).

2. If \( ||w_{i,t} - w_{j,t}|| > \bar{TCB}_{i,t} + \bar{TCB}_{j,t} \) then
\[ ||u_i - u_j|| \geq \gamma \]
holds with probability at least \( 1 - \delta \), uniformly over \( i, j \in V \) and \( t = 0, 1, 2, \ldots \).

**Proof.** 1. We have
\[
\gamma \leq ||u_i - u_j|| \\
= ||u_i - w_{i,t} + w_{i,t} - w_{j,t} + w_{j,t} - u_j|| \\
\leq ||u_i - w_{i,t}|| + ||w_{i,t} - w_{j,t}|| + ||w_{j,t} - u_j|| \\
\leq \bar{TCB}_{i,t} + ||w_{i,t} - w_{j,t}|| + \bar{TCB}_{j,t} \\
(\text{from Lemma 2}) \\
\leq ||w_{i,t} - w_{j,t}|| + \gamma/2, \\
\]
i.e., \( ||w_{i,t} - w_{j,t}|| \geq \gamma/2 > \bar{TCB}_{i,t} + \bar{TCB}_{j,t} \).

2. Similarly, we have
\[
\bar{TCB}_{i,t} + \bar{TCB}_{j,t} < ||w_{i,t} - w_{j,t}|| \\
\leq ||u_i - w_{i,t}|| + ||u_i - u_j|| \\
+ ||w_{j,t} - u_j|| \\
\leq \bar{TCB}_{i,t} + ||u_i - u_j|| + \bar{TCB}_{j,t}, \\
\]
implicating \( ||u_i - u_j|| > 0 \). By the well-separatedness assumption, it must be the case that \( ||u_i - u_j|| \geq \gamma \).

\( \square \)

From Lemma 3, it follows that if any two nodes \( i \) and \( j \) belong to different true clusters and the upper confidence bounds \( \bar{TCB}_{i,t} \) and \( \bar{TCB}_{j,t} \) are both small enough, then it is very likely that edge \((i, j)\) will get deleted by the algorithm (Lemma 3, Item 1). Conversely, if the algorithm deletes an edge \((i, j)\), then it is very likely that the two involved nodes \( i \) and \( j \) belong to different true clusters (Lemma 3, Item 2). Notice that, we have \( E \subseteq E_t \) with high probability for all \( t \). Because the clusters \( V_1, \ldots, V_m \) are induced by the connected components of \( G_t = (V, E_t) \), every true cluster \( V_i \) must be entirely included (with high probability) in some cluster \( V_{j,t} \). Said differently, for all rounds \( t \), the partition of \( V \) produced by \( V_1, \ldots, V_m \) is likely to be a refinement of the one produced by \( V_{1,t}, \ldots, V_{m,t} \) (in passing, this also shows that, with high probability, \( m_t \leq m \) for all \( t \)). This is a key property to all our analysis. See Figure 2 in the main text for reference.

**Lemma 4.** Under the same assumptions as in Lemma 1, if \( j_i \) is the index of the current cluster node \( i \) belongs to, then we have
\[ TCB_{j_i,t-1}(x) \leq \bar{TCB}_{j_i,t-1} \]
holds with probability at least \( 1 - \delta/2 \), uniformly over all rounds \( t = 1, 2, \ldots \), and \( x \in \mathbb{R}^d \) such that \( ||x|| = 1 \).

**Proof.** The proof is the same as the one of Lemma 1, except that at the very end we need to stratify over all possible shapes for cluster \( V_{j_i,t} \), rather than over the \( n \) nodes. Now, since with high probability (Lemma 3), \( V_{j_i,t} \) is the union of true clusters, the set of all such unions is with the same probability upper bounded by \( 2^m \).

\( \square \)
The next lemma is a generalization of Theorem 1 in (Abbasi-Yadkori et al., 2011), and shows a convergence result for aggregate vector $\tilde{w}_{j,t-1}$.

**Lemma 5.** Let $t$ be any round, and assume the partition of $V$ produced by true clusters $V_1, \ldots, V_m$ is a refinement of the one produced by the current clusters $V_{1,t}, \ldots, V_{m,t}$. Let $j = \hat{j}$ be the index of the current cluster node $i_s$ belongs to. Let this cluster be the union of true clusters $V_{j_1}, V_{j_2}, \ldots, V_{j_s}$, associated with (distinct) parameter vectors $u_{j_1}, u_{j_2}, \ldots, u_{j_s}$, respectively. Define

$$\tilde{u}_t = M_{j,t-1}^{-1} \left( \sum_{\ell=1}^k \left( \frac{1}{k} I + \sum_{i \in V_{j_\ell}} (M_{i,t-1} - I) \right) u_{j_\ell} \right).$$

Then:

1. Under the same assumptions as in Lemma 1,

$$||\tilde{u}_t - \tilde{w}_{j,t-1}|| \leq \sqrt{3m TCB_{j,t-1}}$$

holds with probability at least $1 - \delta$, uniformly over cluster indices $j = 1, \ldots, m_s$, and rounds $t = 1, 2, \ldots$.

2. For any fixed $u \in \mathbb{R}^d$ we have

$$||\tilde{u}_t - u|| \leq 2 \sum_{\ell=1}^k ||u_{j_\ell} - u|| \leq 2 SD(u).$$

**Proof.** Let $X_{\ell,t-1}$ be the matrix whose columns are the $d$-dimensional vectors $x_s$, for all $s < t : i_s \in V_{j_\ell}$, $a_{\ell,t-1}$ be the column vector collecting all payoffs $\alpha_s$, $s < t : i_s \in V_{j_\ell}$, and $\eta_{\ell,t-1}$ be the corresponding column vector of noise values. We have

$$\tilde{w}_{j,t-1} = M_{j,t-1}^{-1} \tilde{b}_{j,t-1},$$

with

$$\tilde{b}_{j,t-1} = \sum_{\ell=1}^k X_{\ell,t-1} a_{\ell,t-1}$$

$$= \sum_{\ell=1}^k X_{\ell,t-1} (X_{\ell,t-1}^T u_{j_\ell} + \eta_{\ell,t-1})$$

$$= \sum_{\ell=1}^k \left( \sum_{i \in V_{j_\ell}} (M_{i,t-1} - I) u_{j_\ell} + X_{\ell,t-1} \eta_{\ell,t-1} \right).$$

Thus

$$\tilde{w}_{j,t-1} - \tilde{u}_t = M_{j,t-1}^{-1} \left( \sum_{\ell=1}^k \left( X_{\ell,t-1} \eta_{\ell,t-1} - \frac{1}{k} u_{j_\ell} \right) \right)$$

and, for any fixed $x \in \mathbb{R}^d : ||x|| = 1$, we have

$$(\tilde{w}_{j,t-1}^T x - u_t^T x)^2 = \left( \sum_{\ell=1}^k (X_{\ell,t-1} \eta_{\ell,t-1} - \frac{1}{k} u_{j_\ell}) \right)^T \tilde{M}_{j,t-1}^{-1} (\tilde{w}_{j,t-1} - \tilde{u}_t)^2$$

$$\leq x^T \tilde{M}_{j,t-1}^{-1} x \left( \sum_{\ell=1}^k (X_{\ell,t-1} \eta_{\ell,t-1} - \frac{1}{k} u_{j_\ell}) \right)^T \tilde{M}_{j,t-1}^{-1} (\tilde{w}_{j,t-1} - \tilde{u}_t)$$

$$\leq 2 x^T \tilde{M}_{j,t-1}^{-1} x \left( \sum_{\ell=1}^k \eta_{\ell,t-1} \right) \tilde{M}_{j,t-1}^{-1} \left( \sum_{\ell=1}^k \eta_{\ell,t-1} \right)$$

$$(\tilde{w}_{j,t-1} - \tilde{u}_t)$$

(assuming $(a+b)^2 \leq 2a^2 + 2b^2$).

We focus on the two terms inside the big braces. Because $V_{j,t}$ is made up of the union of true clusters, we can stratify over the set of all such unions (which are at most $2^m$ with high probability), and then apply the martingale result in (Abbasi-Yadkori et al., 2011) (Theorem 1 therein), showing that

$$\left( \sum_{\ell=1}^k X_{\ell,t-1} \eta_{\ell,t-1} \right)^T \tilde{M}_{j,t-1}^{-1} \left( \sum_{\ell=1}^k X_{\ell,t-1} \eta_{\ell,t-1} \right) \leq 2 \sigma^2 \left( \log \frac{|M_{j,t-1}|}{\delta/2^{m+1}} \right)$$

holds with probability at least $1 - \delta/2$. As for the second term, we simply write

$$\frac{1}{k^2} \left( \sum_{\ell=1}^k u_{j_\ell} \right)^T \tilde{M}_{j,t-1}^{-1} \left( \sum_{\ell=1}^k u_{j_\ell} \right) \leq \frac{1}{k^2} \left( \sum_{\ell=1}^k u_{j_\ell} \right)^2 \leq 1.$$

Putting together and overapproximating we conclude that

$$||\tilde{w}_{j,t-1} - \tilde{u}_t|| \leq \sqrt{3m TCB_{j,t-1}} (x)$$

and, since this holds for all unit-norm $x$, Lemma 4 yields

$$||\tilde{w}_{j,t-1} - \tilde{u}_t|| \leq \sqrt{3m TCB_{j,t-1}},$$

thereby concluding the proof of part 1.

As for part 2, because

$$\tilde{M}_{j,t-1} = I + \sum_{\ell=1}^k \sum_{i \in V_{j_\ell}} (M_{i,t-1} - I),$$
we can rewrite \( u \) as
\[
\bar{u}_t - u = \bar{M}^{-1}_{j,t-1} \left( \frac{1}{k} \sum_{\ell=1}^{k} (u_{j\ell} - u) \right)
+ \sum_{\ell=1}^{k} \sum_{i \in V_{j\ell}} (M_{i,t-1} - I) (u_{j\ell} - u).
\]

Hence
\[
||\bar{u}_t - u|| \leq \frac{1}{k} \left| \left| \bar{M}^{-1}_{j,t-1} \sum_{\ell=1}^{k} (u_{j\ell} - u) \right| \right|
+ \sum_{\ell=1}^{k} \left| \left| \bar{M}^{-1}_{j,t-1} \sum_{i \in V_{j\ell}} (M_{i,t-1} - I) (u_{j\ell} - u) \right| \right|
\leq \frac{1}{k} \sum_{\ell=1}^{k} ||u_{j\ell} - u|| + \sum_{\ell=1}^{k} ||u_{j\ell} - u||
\leq 2 \sum_{\ell=1}^{k} ||u_{j\ell} - u||,
\]
as claimed.

Proof. The proof follows from simple but annoying calculations, and is therefore omitted.

We are now ready to combine all previous lemmas into the proof of Theorem 1.

Proof. Let \( t \) be a generic round, \( j_t \) be the index of the current cluster node \( i_t \) belongs to, and \( j_e \) be the index of the true cluster \( i_e \) belongs to. Also, let us define the aggregate vector \( w_{j_t,t-1} \) as follows:
\[
w_{j_t,t-1} = \bar{M}^{-1}_{j_t,t-1} \bar{b}_{j_t,t-1} \quad \text{and} \quad \bar{b}_{j_t,t-1} = \sum_{i \in V_{j_t}} b_{i,t-1}.
\]

Assume Lemma 3 holds, implying that the current cluster \( V_{j_t} \) is the (disjoint) union of true clusters, and define the aggregate vector \( \bar{u}_t \) accordingly, as in the statement of Lemma 5. Notice that \( w_{j_t,t-1} \) is the true cluster counterpart to \( \bar{w}_{j_t,t-1} \), that is, \( \bar{w}_{j_t,t-1} = \bar{w}_{j_t,t-1} - w_{j_t,t-1} \) if \( V_{j_t} = V_{j_t} \). Also, observe that \( \bar{u}_t = u_{i_t} \) when \( V_{j_t} = V_{j_t} \). Finally, set for brevity
\[
x_t^* = \arg\max_{k=1,\ldots,n} u_{i_t}^\top x_{t,k}.
\]

We can rewrite the time-\( t \) regret \( r_t \) as follows:
\[
r_t = u_{i_t}^\top x_t^* - u_{i_t}^\top x_t
\]
\[
= u_{i_t}^\top x_t^* - \bar{w}_{j_t,t-1} x_t^* + \bar{w}_{j_t,t-1} x_t^* - \bar{w}_{j_t,t-1} x_t^*
\]
\[
+ \bar{w}_{j_t,t-1} x_t^* - \bar{w}_{j_t,t-1} x_t + \bar{w}_{j_t,t-1} x_t - u_{i_t}^\top x_t.
\]

Combined with
\[
\bar{w}_{j_t,t-1} x_t^* + \text{TCB}_{j_t,t-1}(x_t^*) \leq \bar{w}_{j_t,t-1} x_t + \text{TCB}_{j_t,t-1}(x_t),
\]
and rearranging gives
\[
r_t \leq u_{i_t}^\top x_t^* - (\bar{w}_{j_t,t-1} x_t + \text{TCB}_{j_t,t-1}(x_t)) \quad (3)
\]
\[
+ (\bar{w}_{j_t,t-1} x_t - u_{i_t}^\top x_t) \quad (4)
\]
\[
+ (\bar{w}_{j_t,t-1} x_t - u_{i_t}^\top x_t). \quad (5)
\]

We continue by bounding with high probability the three terms (3), (4), and (5).

As for (3), and (4), we simply observe that Lemma 2 allows\footnote{This lemma applies here since, by definition, \( \bar{w}_{j_t,t-1} \) is built only from payoffs from nodes in \( V_{j_t} \), sharing the common unknown vector \( u_{i_t} \).} us to write
\[
u_{i_t}^\top x_t^* - (\bar{w}_{j_t,t-1} x_t + \text{TCB}_{j_t,t-1}(x_t)) \leq ||u_{i_t} - \bar{w}_{j_t,t-1}|| \leq \text{TCB}_{j_t,t-1},
\]

and
\[\tilde{w}_{j,t-1}^T \hat{x}_t - u_i^T \tilde{x}_t \leq ||u_i - \tilde{w}_{j,t-1}|| \leq \tilde{\text{TCB}}_{j,t-1}.\]

Moreover,
\[\text{TCB}_{j,t-1}(\tilde{x}_t) \leq \tilde{\text{TCB}}_{j,t-1}\]
(by Lemma 4)
\[\leq \tilde{\text{TCB}}_{j,t-1}-1\]
(by Lemma 3 and the definition of \(\hat{j}_t\)).

Hence,
\[(3) + (4) \leq 3\tilde{\text{TCB}}_{j,t-1}(6)\] holds with probability at least \(1 - 2\delta\), uniformly over \(t\).

As for (5), letting \(\{\cdot\}\) be the indicator function of the predicate at argument, we can write
\[\begin{aligned}
& (\tilde{w}_{j,t-1} - \tilde{w}_{j,t-1})^T (x_i^T - \tilde{x}_t) \\
= & (\tilde{w}_{j,t-1} - \tilde{u}_t)^T (x_i^T - \tilde{x}_t) + (u_i - \tilde{u}_t)^T (x_i^T - \tilde{x}_t) \\
\leq & 2 \text{TCB}_{j,t-1} + 2||u_i - \tilde{u}_t|| + 2\sqrt{3m} \text{TCB}_{j,t-1}
\end{aligned}\]
(using Lemma 2, \(||x_i^T - \tilde{x}_t|| \leq 2\), and Lemma 5, part 1)
\[= 2 \text{TCB}_{j,t-1} + 2 \{V_{j_t} \neq \hat{V}_{j_t,t}\} \{||u_i - \tilde{u}_t||\}
+ 2\sqrt{3m} \text{TCB}_{j,t-1}
\leq \leq (5 + 2\sqrt{3m}) \text{TCB}_{j,t-1} + 4 \{V_{j_t} \neq \hat{V}_{j_t,t}\} \text{SD}(u_i)
\]
(by Lemma 3, and Lemma 5, part 2).

Piecing together we have so far obtained
\[r_t \leq (5 + 2\sqrt{3m}) \text{TCB}_{j,t-1}
+ 4 \{V_{j_t} \neq \hat{V}_{j_t,t}\} \text{SD}(u_i).
\]

We continue by bounding \(\{V_{j_t} \neq \hat{V}_{j_t,t}\}\). From Lemma 3, we clearly have
\[\begin{aligned}
& \{V_{j_t} \neq \hat{V}_{j_t,t}\}
\leq & \{\exists i \in V_j : \forall j \notin V_j : (i,j) \in E_t\}
\leq & \{\exists i \in V_j : \forall j \notin V_j : \forall s < t \ (i,s) \neq i\}
\vee (i,s = i, ||w_{i,s-1} + w_{j,s-1}|| \leq \text{TCB}_{i,s-1} + \text{TCB}_{j,s-1})
\leq & \{\exists i \in V_j : \forall s < t \ i_s \neq i\}
+ \{\exists i \in V_j : \forall j \notin V_j : \forall s < t \text{TCB}_{i,s-1} + \text{TCB}_{j,s-1} \geq \gamma/2\}
\leq & \{\exists i \in V_j : \forall s < t \ i_s \neq i\}
+ \{\exists i \in V_j : \forall j \notin V_j : \forall s < t \text{TCB}_{i,s-1} \geq \gamma/4\}
+ \{\exists i \in V : \forall s < t \text{TCB}_{i,s-1} \geq \gamma/4\}.
\]

At this point, we apply Lemma 6 to \(\tilde{\text{TCB}}_{j,t}\) with
\[A^2 = \left(\sigma \sqrt{2d \log(1+T) + 2 \log(2/\delta)} + 1\right)^2
\leq 4\sigma^2 (d \log(1+T) + \log(2/\delta)) + 2,\]
and set for brevity
\[B = \frac{32}{\lambda} \max\left\{A^2 \frac{64}{\lambda} \log \left(\frac{2nd}{\delta}\right)
\times \log \left(\frac{32\delta}{\lambda} \log \left(\frac{2^d d}{\delta}\right)\right)\right\},
\]
\[C = \frac{2 \cdot 32^2}{\lambda^2} \log \left(\frac{2^m d}{\delta}\right) \log \left(\frac{32\delta}{\lambda} \log \left(\frac{2^m d}{\delta}\right)\right).\]

We can write
\[\{\exists i \in V : \forall s < t \tilde{\text{TCB}}_{i,s-1} \geq \gamma/4\}
\leq \{\exists i \in V : \tilde{\text{TCB}}_{i,t-2} \geq \gamma/4\}
\leq \{\exists i \in V : T_{i,t-2} \leq B\}.
\]

Moreover,
\[\{\exists i \in V_j : \forall s < t i_s \neq i\}
\leq \{\exists i \in V_j : T_{i,t-1} = 0\}
\leq \{\exists i \in V : T_{i,t-1} = 0\}.
\]

That is,
\[\{V_{j_t} \neq \hat{V}_{j_t,t}\} \leq \{\exists i \in V : T_{i,t-2} \leq B\}
+ \{\exists i \in V : T_{i,t-1} = 0\}.
\]

Further, using again Lemma 6 (applied this time to \(\tilde{\text{TCB}}_{j,t}\)) combined with the fact that \(\tilde{\text{TCB}}_{j,t} \leq A\) for all \(j\) and \(t\), we have
\[\tilde{\text{TCB}}_{j,t-1} = A \{T_{j,t-1} < C\} + \frac{A}{\sqrt{1 + \lambda T_{j,t-1} / 8}},\]
where
\[T_{j,t-1} = \sum_{i \in V_j} T_{i,t-1} = \{|s \leq t-1 : i_s \in V_j\}|.\]

Putting together as in (7), and summing over \(t = 1, \ldots, T\), we have shown so far that with probability at least \(1 - 7\delta/2,\)
\[\sum_{t=1}^{T} r_t \leq (5 + 2\sqrt{3m}) A \sum_{t=1}^{T} \{T_{j,t-1} < C\}
+ \frac{A}{\sqrt{1 + \lambda T_{j,t-1} / 8}}
\]
\[+ 4 \sum_{t=1}^{T} \text{SD}(u_i) \{\exists i \in V : T_{i,t-2} \leq B\}
+ 4 \sum_{t=1}^{T} \text{SD}(u_i) \{\exists i \in V : T_{i,t-1} = 0\},\]
with $T_{i,t} = 0$ if $t \leq 0$.

We continue by upper bounding with high probability the four terms in the right-hand side of the last inequality. First, observe that for any fixed $i$ and $t$, $T_{i,t}$ is a binomial random variable with parameters $t$ and $1/n$, and $T_{j,t-1} = \sum_{i \in V_{j,t-1}} T_{i,t-1}$ which, for fixed $i$, is again binomial with parameters $t$ and $2/n$, where $n_{j,t}$ is the size of the true cluster $i_t$ falls into. Moreover, for any fixed $t$, the variables $T_{i,t}$, $i \in V$ are independent.

To bound the third term, we use a standard Bernstein inequality twice: first, we apply it to sequences of independent Bernoulli variables, whose sum $T_{i,t-2}$ has average $\mathbb{E}[T_{i,t-2}] = \frac{t-2}{n}$ (for $t \geq 3$), and then to the sequence of variables $SD(u_{i,t})$ whose average $\mathbb{E}[SD(u_{i,t})] = \frac{1}{n} \sum_{i \in V} SD(u_{i})$ is over the random choice of $i_t$.

Setting for brevity

$$D(B) = 2n \left( B + \frac{5}{3} \log(Tn/\delta) \right) + 2,$$

where $B$ has been defined before, we can write

$$\sum_{t=1}^{T} SD(u_{i,t}) \{ \exists i \in V : T_{i,t-2} \leq B \}$$

$$= \sum_{t \leq D(B)} SD(u_{i,t}) \{ \exists i \in V : T_{i,t-2} \leq B \}$$

$$+ \sum_{t > D(B)} SD(u_{i,t}) \{ \exists i \in V : T_{i,t-2} \leq B \}$$

$$\leq \sum_{t \leq D(B)} SD(u_{i,t})$$

$$+ m \sum_{t > D(B)} \{ \exists i \in V : T_{i,t-2} \leq B \}.$$

Then from Bernstein’s inequality,

$$\mathbb{P} \left( \exists i \in V \exists t > D(B) : T_{i,t-2} \leq B \right) \leq \delta,$$

and

$$\mathbb{P} \left( \sum_{t \leq D(B)} SD(u_{i,t}) \geq \frac{3}{2} D(B) \mathbb{E}[SD(u_{i,t})] \right.$$ 

$$+ \frac{5}{3} m \log(1/\delta) \left. \right) \leq \delta.$$

Thus with probability $\geq 1 - 2\delta$

$$\sum_{t=1}^{T} SD(u_{i,t}) \{ \exists i \in V : T_{i,t-2} \leq B \}$$

$$\leq \frac{3}{2} D(B) \mathbb{E}[SD(u_{i,t})] + \frac{5}{3} m \log(1/\delta).$$

Similarly, to bound the fourth term we have, with probability $\geq 1 - 2\delta$,

$$\sum_{t=1}^{T} SD(u_{i,t}) \{ \exists i \in V : T_{i,t-1} = 0 \}$$

$$\leq \frac{3}{2} D(0) \mathbb{E}[SD(u_{i,t})] + \frac{5}{3} m \log(1/\delta).$$

Next, we crudely upper bound the first term as

$$(5 + 2\sqrt{3m}) A \sum_{t=1}^{T} \{ T_{j,t-1} < C \}$$

$$\leq (5 + 2\sqrt{3m}) A \sum_{t=1}^{T} \{ T_{i,t-1} < C \},$$

and then apply a very similar argument as before to show that with probability $\geq 1 - \delta$,

$$\sum_{t=1}^{T} \{ T_{i,t-1} < C \} \leq n \left( C + \frac{5}{3} \log \left( \frac{T}{\delta} \right) \right) + 1.$$

Finally, we are left to bound the second term. The following is a simple property of binomial random variables we be useful.

**Claim 2.** Let $X$ be a binomial random variable with parameters $n$ and $p$, and $\lambda \in (0, 1)$ be a constant. Then

$$\mathbb{E} \left[ \frac{1}{\sqrt{1 + \lambda X}} \right] \leq \begin{cases} 3 \sqrt{1 + \lambda X} & \text{if } np \geq 10; \\ 1 & \text{if } np < 10. \end{cases}$$

**Proof of claim.** The second branch of the inequality is clearly trivial, so we focus on the first one under the assumption $np \geq 10$. Let then $\beta \in (0, 1)$ be a parameter that will be set later on. We have

$$\mathbb{E} \left[ \frac{1}{\sqrt{1 + \lambda X}} \right] \leq \mathbb{P}(X \leq (1 - \beta) np)$$

$$+ \frac{1}{\sqrt{1 + \lambda (1 - \beta) np}} \mathbb{P}(X \geq (1 - \beta) np)$$

$$\leq e^{-\beta^2 np/2} + \frac{1}{\sqrt{1 + \lambda (1 - \beta) np}},$$

the last inequality following from the standard Chernoff
bounds. Setting \( \beta = \sqrt{\log(1+\lambda n p)/n p} \) gives

\[
E \left[ \frac{1}{\sqrt{1+\lambda X}} \right] \leq \frac{1}{\sqrt{1+\lambda n p}} + \frac{1}{\sqrt{1+\lambda (np - \sqrt{np \log(1+\lambda np)})}}
\]

\[
\leq \frac{1}{\sqrt{1+\lambda n p}} + \frac{1}{\sqrt{1+\lambda n p/2}}
\]

(assuming \( np \geq 10 \))

i.e., the claimed inequality

Now,

\[
E_{t-1} \left[ \frac{1}{\sqrt{1+\lambda T_{j,t-1}/8}} \right] = \sum_{j=1}^{m} \frac{v_j}{n} \sqrt{1+\lambda T_{j,t-1}/8},
\]

being \( T_{j,t-1} = |\{s < t : i_s \in V_j\}| \) a binomial variable with parameters \( t-1 \) and \( v_j/n \), where \( v_j = |V_j| \). By the standard Hoeffding-Azuma inequality

\[
\sum_{t=1}^{T} \frac{1}{\sqrt{1+\lambda T_{j,t-1}/8}} \leq \sum_{t=1}^{T} \frac{m}{n} \sqrt{1+\lambda T_{j,t-1}/8} + \sqrt{2T \log(1/\delta)}
\]

holds with probability at least \( 1 - \delta \). In turn, from Bernstein’s inequality, we have

\[
P( \exists t \not\exists j : T_{j,t-1} \leq \frac{t-1}{2n} v_j - \frac{5}{3} \log(Tm/\delta) ) \leq \delta.
\]

Therefore, with probability at least \( 1 - 2\delta \),

\[
\sum_{t=1}^{T} \frac{1}{\sqrt{1+\lambda T_{j,t-1}/8}} \leq \sum_{t=1}^{T} \frac{m}{n} \frac{v_j}{\sqrt{1+\lambda (t-1)/8}} v_j - \frac{5}{3} \log(Tm/\delta) + \sqrt{2T \log(1/\delta)}
\]

\[
\leq \sum_{j=1}^{m} \frac{v_j}{n} \left( 4n \frac{5}{3} \log(Tm/\delta) + 1 + \sum_{t=1}^{T} \frac{1}{\sqrt{1 + \frac{t-1}{8} v_j}} \right) v_j + \sqrt{2T \log(1/\delta)}
\]

\[
= 4n \frac{5}{3} \log(Tm/\delta) + 1 + \sum_{j=1}^{m} \frac{v_j}{n} \sum_{t=1}^{T} \frac{1}{\sqrt{1 + \frac{t-1}{4n} v_j}} v_j + \sqrt{2T \log(1/\delta)}.
\]

If we set for brevity \( r_j = \frac{\lambda}{8} v_j/n, j = 1, \ldots, m \), we have

\[
\sum_{t=1}^{T} \frac{1}{\sqrt{1 + \frac{\lambda}{8} (t-1)/n}} v_j \leq \int_{0}^{T} \frac{dx}{\sqrt{1 + (x-1)r_j}}
\]

\[
= \frac{2}{r_j} \left( \sqrt{1 + Tr_j} - r_j - \sqrt{1 - r_j} \right)
\]

\[
\leq 2 \sqrt{T/r_j},
\]

so that

\[
\sum_{t=1}^{T} \frac{1}{\sqrt{1 + \lambda T_{j,t-1}/8}} \leq 4n \frac{5}{3} \log(Tm/\delta) + 1 + \sqrt{2T \log(1/\delta)} + 8 \sum_{j=1}^{m} \sqrt{2T v_j/\lambda n}.
\]

Finally, we put all pieces together. In order for all claims to hold simultaneously with probability at least \( 1 - \delta \), we need to replace \( \delta \) throughout by \( \delta/10.5 \). Then we switch to a \( \tilde{O} \)-notation, and overapproximate once more to conclude the proof.

2. Implementation

As we said in the main text, in implementing the algorithm in Figure 1, the reader should keep in mind that it is reasonable to expect \( n \) (the number of users) to be quite large, \( d \) (the number of features of each item) to be relatively small, and \( m \) (the number of true clusters) to be very small compared to \( n \). Then the algorithm can be implemented by storing a least-squares estimator \( \omega_{i,t-1} \) at each node \( i \in V \), an aggregate least squares estimator \( \Omega_{j,t-1} \) for each current cluster \( j \in \{1, \ldots, m\} \), and an extra data-structure which is able to perform decremental dynamic connectivity. Fast implementations of such data-structures are those studied by (Thorup, 1997; Kapron et al., 2013) (see also the research thread referenced therein). In particular, in (Thorup, 1997) (Theorem 1.1 therein) it is shown that a randomized construction exists that maintains a spanning forest which, given an initial undirected graph \( G_1 = (V, E_1) \), is able to perform edge deletions and answer connectivity queries of the form “Is node \( i \) connected to node \( j \)” in expected total time \( O\left( \min\{|V|^2, |E_1| \log |V| \} + \sqrt{|V||E_1| \log^{2.5} |V|} \right) \) for \( E_1 \) deletions. Connectivity queries and deletions can be interleaved, the former being performed in constant time. Notice that when we start off from the full graph, we have \( |E_1| = O(|V|^2) \), so that the expected amortized time per query becomes constant. On the other hand, if our initial graph has \( |E_1| = O(|V| \log |V|) \) edges, then the expected amortized time per query is \( O(\log^2 |V|) \). This
becomes $O(\log^{2.5} |V|)$ if the initial graph has $|E_1| = O(|V|)$. In addition, we maintain an $n$-dimensional vector \textsc{ClusterIndices} containing, for each node $i \in V$, the index $j$ of the current cluster $i$ belongs to.

With these data-structures handy, we can implement our algorithm as follows. After receiving $i_t$, computing $k_t$ is $O(1)$ (just by accessing \textsc{ClusterIndices}). Then, computing $c_t$ can be done in time $O(d^2)$ (matrix-vector multiplication, executed $c_t$ times, assuming $c_t$ is a constant). Then the algorithm directly updates $b_{i_t,t-1}$ and $b_{j_t,t-1}$, as well as the inverses of matrices $M_{i_t,t-1}$ and $M_{j_t,t-1}$, which is again $O(d^2)$, using standard formulas for rank-one adjustment of inverse matrices. In order to prepare the ground for the subsequent edge deletion phase, it is convenient that the algorithm also stores at each node $i$ matrix $M_{i,t-1}$ (whose time-$t$ update is again $O(d^2)$).

Let $\text{DELETE}(i,t)$ and $\text{IS-CONNECTED}(i,\ell)$ be the two operations delivered by the decremental dynamic connectivity data-structure. Edge deletion at time $t$ corresponds to cycling through all nodes $\ell$ such that $(i_t, \ell)$ is an existing edge. The number of such edges is on average equal to the average degree of node $i_t$, which is $O\left(\frac{|E_1|}{n}\right)$, where $|E_1|$ is the number of edges in the initial graph $G_1$. Now, if $(i_t, \ell)$ has to be deleted (each the deletion test being $O(d)$), then we invoke $\text{DELETE}(i_t, t)$, and then $\text{IS-CONNECTED}(i_t, \ell)$.

If $\text{IS-CONNECTED}(i_t, \ell) = \text{"no"}$, this means that the current cluster $C_{j_t,t-1}$ has to split into two new clusters as a consequence of the deletion of edge $(i_t, \ell)$. The set of nodes contained in these two clusters correspond to the two sets

\[
\{ k \in V : \text{IS-CONNECTED}(i_t, k) = \text{"yes"} \}, \\
\{ k \in V : \text{IS-CONNECTED}(\ell, k) = \text{"yes"} \},
\]

whose expected amortized computation per node is $O(1)$ to $O(\log^{2.5} n)$ (depending on the density of the initial graph $G_1$). We modify the \textsc{ClusterIndices} vector accordingly, but also the aggregate least squares estimators. This is because $\bar{m}_{j_t,t-1}$ (represented through $M_{j_t,t-1}^{-1}$) and $b_{j_t,t}$ has to be spread over the two new clusters. This operation can be performed by adding up all matrices $M_{i,t}$ and all $b_{i,t}$, over all $i$ belonging to each of the two new clusters (it is at this point that we need to access $M_{i,t}$ for each $i$), and then inverting the resulting aggregate matrices. This operation takes $O(n d^2 + d^3)$. However, as argued in the comments following Lemma 3, with high probability the number of current clusters $m_t$ can never exceed $m$, so that with the same probability this operation is only performed at most $m$ times throughout the learning process. Hence in $T$ rounds we have an overall (expected) running time

\[
O\left(T \left( d^2 + \frac{|E_1|}{n} d \right) + m (n d^2 + d^3) + |E_1| \right)
\]

\[+ \min\{n^2, |E_1| \log n\} + \sqrt{n |E_1| \log^{2.5} n} \right).
\]

Notice that the above is $n \cdot \text{poly}(\log n)$, so if so is $|E_1|$. In addition, if $T$ is large compared to $n$ and $d$, the average running time per round becomes $O(d^2 + d \cdot \text{poly}(\log n))$.

As for memory requirements, we need to store two $d \times d$ matrices and one $d$-dimensional vector at each node, one $d \times d$ matrix and one $d$-dimensional vector for each current cluster, vector \textsc{ClusterIndices}, and the data-structures allowing for fast deletion and connectivity tests. Overall, these data-structures do not require more than $O(|E_1|)$ memory to be stored, so that this implementation takes $O(n d^2 + m d^2 + |E_1|) = O(n d^2 + |E_1|)$, where we again relied upon the $m_t \leq m$ condition. Again, this is $n \cdot \text{poly}(\log n)$ if so is $|E_1|$. 

### 3. Further Plots

This section contains a more thorough set of comparative plots on the synthetic datasets described in the main text. See Figure 1 and Figure 2.

### 4. Derivation of the Reference Bounds

We now provide a proof sketch of the reference bounds mentioned in Section 2 of the main text.

Let us start off from the single user bound for LINUCB (either ONE or IND) one can extract from (Abbasi-Yadkori et al., 2011). Let $u_j \in \mathbb{R}^d$ be the profile vector of this user. Then, with probability at least $1 - \delta$, we have

\[
\sum_{t=1}^{T} r_t = O\left( \sqrt{T \left( \sigma^2 d \log T + \sigma^2 \log \frac{1}{\delta} + \|u_i\|^2 \right) d \log T} \right)
\]

\[= \tilde{O}\left( \sqrt{T \left( \sigma^2 d + \|u_j\|^2 \right) d} \right)
\]

\[= \tilde{O}\left( \sigma d + \sqrt{d} \sqrt{T} \right),
\]

the last line following from assuming $\|u_j\| = 1$.

Then, a straightforward way of turning this bound into a bound for the CLEARVOYANT algorithm that knows all clusters $V_1, \ldots, V_m$ ahead of time and runs one instance of LINUCB per cluster is to sum the regret contributed by each cluster throughout the $T$ rounds. Letting $T_{j,T}$ denote
the authors define a transfer learning problem within a stochastic multiarmed bandit setting, where a prior distribution is defined over the set of possible models over the tasks. More similar in spirit to our paper is the recent work (Brunskill & Li, 2013) that relies on clustering Markov Decision Processes based on their model parameter similarity. A paper sharing significant similarities with ours, in terms of both setting and technical tools is the very recent paper (Maillard & Mannor, 2014). In (Azar et al., 2013), the authors define a transfer learning problem within a stochastic multiarmed bandit setting, where a prior distribution is defined over the set of possible models over the tasks. More similar in spirit to our paper is the recent work (Brunskill & Li, 2013) that relies on clustering Markov Decision Processes based on their model parameter similarity. A paper sharing significant similarities with ours, in terms of both setting and technical tools is the very recent paper (Maillard & Mannor, 2014) that came to our attention at the time of writing ours. In that paper, the authors analyze a noncontextual stochastic bandit problem where model parameters can indeed be clus-
tered in a few (unknown) types, thereby requiring the algorithm to learn the clusters rather than learning the parameters in isolation. Yet, the provided algorithmic solutions are completely different from ours. Finally, in (Djolonga et al., 2013), the authors work under the assumption that users are defined using a context vector, and try to learn a low-rank subspace under the assumption that variation across users is low-rank. The paper combines low-rank matrix recovery with high-dimensional Gaussian Process Bandits, but it gives rise to algorithms which do not seem easy to use in large scale practical scenarios.

7. Ongoing Research

This work could be extended along several directions. First, we may rely on a softer notion of clustering than the one we adopted here: a cluster is made up of nodes where the “within distance” between associated profile vectors is smaller than their “between distance”. Yet, this is likely to require prior knowledge of either the distance threshold or the number of underlying clusters, which are assumed to be unknown in this paper. Second, it might be possible to handle partially overlapping clusters. Third, CLUB can clearly be modified so as to cluster nodes through off-the-shelf graph clustering techniques (mincut, spectral clustering, etc.). Clustering via connected components has the twofold advantage of being computationally faster and relatively easy to analyze. In fact, we do not know how to analyze CLUB when combined with alternative clustering techniques, and we suspect that Theorem 1 already delivers the sharpest results (as $T \to \infty$) when clustering is indeed based on connected components only. Fourth, from a practical standpoint, it would be important to incorporate further side information, like must-link and cannot-link constraints. Fifth, in recommender system practice, it is often relevant to provide recommendations to new users, even in the absence of past information (the so-called “cold start” problem). In fact, there is a way of tackling this problem through the machinery we developed here (the idea is to duplicate the newcomer’s node as many times as the current clusters are, and then treat each copy as a separate user). This would potentially allow CLUB to work even in the presence of (almost) idle users. We haven’t so far collected any experimental evidence on the effectiveness of this strategy. Sixth, following the comments we made in Remark 3, we are trying to see if the i.i.d. and other statistical assumptions we made in Theorem 1 could be removed.
