## Supplementary Materials

## 1. DEMO: Differential Evolution for Multi-Objective Optimization

The DEMO (Differential Evolution for Multi-Objective, Robič \& Filipič (2005)) algorithm is used for the multiobjective optimization of acquisition functions, we briefly introduce the algorithm in this section. It should be noted that other multi-objective optimization algorithms can also be used for the proposed MACE algorithm.
The DEMO algorithm follows the basic procedure of evolutionary algorithms. Firstly, a set of points are randomly sampled to form the initial population, at each iteration, random variations are added to parent population via mutation and crossover to generate the children population, the parent population and children population are compared to create the parent population for the next generation. During the evolution, the Pareto front is recorded. The DEMO algorithm is summarized in Algorithm 1.

```
Algorithm 1 DEMO
    Randomly sample the \(N\) points in the design space to
    form the initial population \(P^{1}\)
    for \(\mathrm{t}=1,2, \ldots G\) do
        \(M^{t}=\) mutation \(\left(P^{t}\right)\)
        \(C^{t}=\operatorname{crossover}\left(P^{t}, M^{t}\right)\)
        \(P^{t+1}=\operatorname{selection}\left(P^{t}, C^{t}\right)\)
    end for
    Return the recorded Pareto front
```

At the $i$-th iteration, we denote the population as $P^{i} \in$ $R^{N \times D}$, where $N$ is the number of population, and $D$ is the dimension of input variables. The mutated population $M^{i} \in R^{N \times D}$ is generated by

$$
\begin{equation*}
M_{j}^{i}=P_{r 1}^{i}+F \times\left(P_{r 2}^{i}-P_{r 3}^{i}\right), j \in\{1 \ldots N P\} \tag{1}
\end{equation*}
$$

where $M_{j}^{i}$ means the $j$-th row of $M^{i}$, while $P_{r 1}^{i}, P_{r 2}^{i}$ and $P_{r 3}^{i}$ are the $r 1$-th, $r 2$-th and $r 3$-th rows of $P^{i}$, the $r 1, r 2$ and $r 3$ are three integers randomly chosen from $[1, N]$. The scaling factor $F \in(0,1)$ is an algorithm parameter to control the mutation.

After the mutation, crossover operations are performed to generated the children population $C^{i} \in R^{N \times D}$. For each element of $C^{i}$, two random numbers $r_{r}$ and $r_{i}$ are generated, $r_{r}$ is a real-valued number uniformly sampled from $(0,1)$,
$r_{i}$ is an integer number uniformly sampled from $[1, D]$, the element of $C^{i}$ is calculated by

$$
C_{j k}^{i}= \begin{cases}P_{j k}^{i} & r_{r}<C R \text { and } r_{i} \neq k  \tag{2}\\ C_{j k}^{i} & \text { otherwise }\end{cases}
$$

where the crossover rate $C R$ is an algorithm parameter to control the crossover.
Now that we have the parent population $P^{i}$ and the children population $C^{i}$, we perform selection to generate the new population $P^{i+1}$. Firstly, an empty archive is created, we perform pair-wise compairsion between parents and children, if one parent solution dominates its child solution, the parent solution is added into the archive; if the child solution dominates its parent, the child is added into the archive; if the parent and its child don't dominate each other, both the parent and the child are added into the archive. After the pair-wise compairsion, non-dominated sorting(Deb et al., 2002) is performed to select $G$ solutions as the parent population of the next generation. The non-dominated sorting method defines a complete order between a group of solutions, details of the non-dominated sorting can be seen in (Deb et al., 2002).
As has been mentioned, four algorithm parameters are to be set for the DEMO algorithm: the population size $N$, the number of generations $G$, the scaling factor $F$ and the crossover rate $C R$. We set $N=100, G=250, F=0.5$ and $C R=0.3$ for all the experiments performed in the paper.

## 2. Additional Experiments with Varied Batch Sizes

We performed additional experiments with varied batch sizes $B=2, B=3$ and $B=5$, the results for the analytical benchmark functions are shown in Table 1, Table 2 and Table 3. The optimization results of the operational amplifier are listed in Table 4, the optimization results of the class-E power amplifier are given in Table 5. With varied batch sizes, the proposed MACE method remain competitive compared with the state-of-the-art batch Bayesian optimization methods.

Table 1. Statistics of the regrets of the benchmark functions with batch size $B=2$

| Algorithm | MACE | BLCB | EI-LP | QKG | QEI |
| :--- | :--- | :--- | :--- | :--- | :--- |
