## Supplementary materials

## A Reverse mode sensitivities derivations

We are interested in reverse mode differentiation. That is, we propagate the gradient backward in the chain of operations from the scalar objective to the upstream parameters.
For a chain of operations $X \rightarrow Y \rightarrow \cdots \rightarrow c$ (with $X, Y$ matrices), we have

$$
d c=\sum_{i j} \frac{\partial c}{\partial Y_{i j}} d Y_{i j}
$$

Noting $\bar{Y}=\left[\frac{\partial c}{\partial Y_{i j}}\right]$, we can rewrite this as $d c=\operatorname{Tr}\left(\bar{Y}^{T} d Y\right)$. When doing reverse mode differentiation, we propagate the errors from the objective. From the mapping from $X \rightarrow Y$, we figure out matrices $L_{X}$ and $R_{X}$ such that $d Y=L_{X}(d X) R_{X}$. It follows that $d c=\operatorname{Tr}\left(\bar{Y}^{T} L_{X}(d X) R_{X}\right)$ and, after a rotation in the trace, we can then identify $\bar{X}^{T}=R_{X} \bar{Y}^{T} L_{X}$.

## A. 1 Outer product $m, v \rightarrow m v^{T}$

$o=m v^{T}$, so $\mathrm{d} o=\mathrm{d} m v^{T}+m \mathrm{~d} v^{T}$
For fixed $m$ : $\mathrm{d} o=m \mathrm{~d} v^{T}$ so

$$
\bar{v}=\bar{o}^{T} m
$$

For fixed $v: \mathrm{d} o=\mathrm{d} m v^{T}$ so

$$
\begin{aligned}
\bar{m}^{T} & =v^{T} \bar{o}^{T} \\
\bar{m} & =\bar{o} v
\end{aligned}
$$

## A. 2 Product $B_{1}^{X}, B_{2}^{Y} \rightarrow B_{1}^{X} B_{2}^{Y}$

$X$ and $Y$ are both either $T$ (for transpose) or 1 (for identity). This allows to write all cases of argument transposition at once.
$P=B_{1}^{X} B_{2}^{Y}$, so d $P=\mathrm{d}\left(B_{1}^{X}\right) B_{2}^{Y}+B_{1}^{X} \mathrm{~d}\left(B_{2}^{Y}\right)$.
For fixed $B_{1}^{X}: \mathrm{d} P=B_{1}^{X} \mathrm{~d}\left(B_{2}^{Y}\right)$ so

$$
\bar{B}_{2}^{Y T}=\bar{P}^{T} B_{1}^{X}=\mathbb{P}\left(\bar{P}^{T}, B_{1}^{X}\right)
$$

For fixed $B_{2}^{Y}: \mathrm{d} P=\mathrm{d}\left(B_{1}^{X}\right) B_{2}^{Y}$ so

$$
\bar{B}_{1}^{X T}=B_{2}^{Y} \bar{P}^{T}=\mathbb{P}\left(B_{2}^{Y}, \bar{P}^{T}\right)
$$

A. 3 Solve $L^{X}, B^{Y} \rightarrow L^{-X} B^{Y}$
$X$ and $Y$ are as defined in the product section.
$S=L^{-X} B^{Y}$, so

$$
\begin{aligned}
\mathrm{d} S & =\mathrm{d}\left(L^{-X}\right) B^{Y}+L^{-X} \mathrm{~d}\left(B^{Y}\right) \\
& =-L^{-X} \mathrm{~d}\left(L^{X}\right) L^{-X} B^{Y}+L^{-X} \mathrm{~d}\left(B^{Y}\right)
\end{aligned}
$$

For fixed $B^{Y}: \mathrm{d} S=-L^{-X} \mathrm{~d}\left(L^{X}\right) L^{-X} B^{Y}$ so $\bar{L}^{X T}=-L^{-X} B^{Y} \bar{S}^{T} L^{-X}$

$$
\begin{aligned}
\bar{L}^{X T} & =-L^{-X} B^{Y} \bar{S}^{T} L^{-X} \\
& =-\left(L^{-X} B^{Y}\right)\left(L^{-X T} \bar{S}\right)^{T} \\
& =-\mathbb{P}\left(\mathbb{S}\left(L^{X}, B^{Y}\right), \mathbb{S}\left(L^{X T}, \bar{S}\right)^{T}\right)
\end{aligned}
$$

For fixed $L^{X}: \mathrm{d} S=L^{-X} \mathrm{~d}\left(B^{Y}\right)$ so

$$
\begin{aligned}
\overline{B^{Y}} & =\bar{S}^{T} L^{-X} \\
\overline{B^{Y}} & =L^{-X T} \bar{S} \\
& =\mathbb{S}\left(L^{X T}, \bar{S}\right) .
\end{aligned}
$$

## A. 4 Product $B, v \rightarrow B v$

$p=B v$, so $\mathrm{d} p=\mathrm{d} B v+B \mathrm{~d} v$.
For fixed $v, \mathrm{~d} p=\mathrm{d} B v$, so

$$
\begin{aligned}
\bar{B}^{T} & =v \bar{p}^{T} \\
\bar{B} & =\mathbb{O}\left(\bar{p}, v^{T}\right)
\end{aligned}
$$

For fixed $B, \mathrm{~d} p=B \mathrm{~d} v$, so

$$
\begin{aligned}
\bar{v}^{T} & =\bar{p}^{T} B \\
\bar{v} & =\mathbb{P}\left(B^{T}, \bar{p}\right) .
\end{aligned}
$$

A. 5 Solve $L, v \rightarrow L^{-1} v$
$u=L^{-1} v$, so

$$
\begin{aligned}
\mathrm{d} u & =\mathrm{d}\left(L^{-1} v\right) \\
& =\mathrm{d}\left(L^{-1}\right) v+L^{-1} \mathrm{~d} v \\
& =-L^{-1}(\mathrm{~d} L) L^{-1} v+L^{-1} \mathrm{~d} v .
\end{aligned}
$$

For fixed $L, \mathrm{~d} u=L^{-1} \mathrm{~d} v$, so

$$
\begin{aligned}
\bar{v}^{T} & =\bar{u}^{T} L^{-1} \\
& =\mathbb{S}\left(L^{T}, u\right)^{T}
\end{aligned}
$$

For fixed $v, \mathrm{~d} u=-L^{-1}(\mathrm{~d} L) L^{-1} v$, so

$$
\begin{aligned}
\bar{L}^{T} & =-L^{-1} v \bar{u}^{T} L^{-1} \\
& =\mathbb{P}\left(\mathbb{S}(L, v), S\left(L^{T}, u\right)^{T}\right) .
\end{aligned}
$$

## B Algorithms

We report algorithms operating on a dense representation of the banded matrices (the usual $i, j$ indexing). In practice these only read and write into the band of the matrices involved as input or output. A derivation using the (diag, column) indexing would reflect this fact more clearly but blurs the inner working of the algorithms. In a similar spirit, our algorithms sometimes include avoidable instantiations of temporary variables that are kept for clarity. For reverse mode differentiation we refer the reader to (Giles, 2008) from which we follow the notation.

```
Algorithm 1 Cholesky algorithm for banded matrices.
Initialize L with zeros
    for \(i\) in 0 to \(n-1\) do
    for \(j\) in \(\max (i-l, 0)\) to \(i+1\) do
        \(m=\max (i-l, j-l, 0)\)
            \(s=\operatorname{sum}(L[i, m: j] * L[j, m: j])\)
            if \(i==j\) then
            \(L[i, j]=\operatorname{sqrt}(Q[i, j]-s)\)
        else
            \(L[i, j]=(Q[i, j]-s) / L[j, j]\)
        end
    end
end
```

Input : $Q$ : an $n \times n$ symmetric positive definite matrix with $l$ lower sub-diagonals.
Output: $L$ : an $n \times n$ lower triangular matrix with $l$ lower sub-diagonals.

```
Input : \(L\) : the \(n \times n\) Cholesky factor of \(Q\), with \(l\) lower sub-diagonals.
Initialize \(Q_{-} b\) with zeros
    for \(i\) in \(\bar{n}-1\) downto 0 do
    \(j \_\)stop \(=\max (i-l, 0)\)
        for \(j\) in \(i\) to \(j_{-}\)stop do
            if \(j==i\) then
                \(\mid Q_{-} b[i, i]=1 / 2 * L \_b[i, i] / L[i, i]\)
            else
                    \(Q \_b[i, j]=L \_b[i, j] / L[j, j]\)
                    \(L \_b[j, j]-=L \_b[i, j] * L[i, j] / L[j, j]\)
            end
            for \(l\) in \(j-1\), in \(j_{-}\)stop do
            \(L \_b[i, l]-=Q \_b[i, j] * L[j, l]\)
                    \(L \_b[j, l]-=Q \_b[i, j] * L[i, l]\)
            end
    end
end
```

Algorithm 2 Reverse mode differentiation for the Cholesky operator for banded matrices.
$L_{-} b$ : the $n \times n$ reverse mode derivatives of $L$ with respect to the objective function.
Output: $Q_{-}^{-} b$ : the $n \times n$ reverse mode derivatives of $Q$ with respect to the objective function.

```
Algorithm 3 Algorithm for the inverse of a matrix from its Cholesky decomposition.
Input : \(L\) : an \(n \times n\) lower triangular matrix with \(l\) lower sub-diagonals.
Output: \(S\) : an \(n \times n\) lower triangular matrix with \(l\) lower sub-diagonals of \(\left[L L^{T}\right]^{-1}\).
Initialize Sym as a (symmetric) \(n \times n\) banded matrix of both lower and upper bandwidth \(l\)
    vec \(=\operatorname{diag}(L)\)
    \(U=\operatorname{transpose}(L / v e c)\)
    for \(j\) in \(n-1\), downto 0 do
    for \(i\) in \(j\) downto \(\max (j-l+1,0)\) do
        \(\operatorname{Sym}[i, j]=-\operatorname{sum}(U[i, i+1: i+l] \operatorname{Sym}[i+1: i+l, j])\)
            \(\operatorname{Sym}[j, i]=\operatorname{Sym}[i, j]\)
            if \(i==j\) then
            \(\operatorname{Sym}[i, i]+=1 /(\operatorname{vec}[i])^{2}\)
        end
    end
end
\(S=\) lower_band(Sym)
```

```
Algorithm 4 Reverse mode differentiation of the inverse from Cholesky.
Input : \(L: L\) : the \(n \times n\) Cholesky factor of \(Q\), with \(l\) lower sub-diagonals.
    \(S\) : The \(n \times n\) output of the subset inverse from Cholesky with \(l\) lower sub-diagonals.
    \(b S\) : the \(n \times n\) reverse mode derivatives of \(B\) with respect to the objective function.
    Note that both \(S\) and bS should be treated as symmetric banded matrices,
    with \(b S\) copied locally (modified in place).
Output: \(b L: n \times n\) the reverse mode derivatives of \(L\) with respect to the objective function.
Initialize \(b U\) as a banded matrix similar to \(U\), filled with zeros.
    Initialize bvec_inv_2 as a vector of size \(n\) filled with zeros.
```

```
\(\operatorname{vec}=\operatorname{diag}(L)\)
```

        \(O(i, i-k)=(r-\) dot_product \() / L(i, i)\)
    end
end
```

## C Pseudocode of algorithms

We here provide details on how we used our operators for banded matrices in the algorithms we proposed. Implementation details are also given for the pre-existing algorithms we used as comparisons.

## C. 1 log likelihood evaluation (for HMC)

In section 3.2, we explained how to perform gradient based MCMC in GMRF models. Algorithm 6 gives some details on how we evaluate the likelihood given sampled parameters $\theta$ and whitened latent $v$.

```
Algorithm 6 Log Likelihood evaluation
Input : white noise sample v}\mathrm{ : vector of length n
        observations Y: vector of length n
        precision Q:n\timesn symmetric matrix with l sub-diagonals
        parameter }0\mathrm{ and density }p(0
Output: Log likelihood 酋p(v,0,Y)
    % Cholesky factor of Q
    L
    % Construct observation sample
    F\leftarrow\mathbb{S}(\mp@subsup{L}{Q}{T},v)
    % Compute log-likelihood
    log}p(v,0,Y)\leftarrow\operatorname{log}p(v)+\operatorname{log}p(0)+\mp@subsup{\sum}{i=1}{n}\operatorname{log}p(\mp@subsup{y}{i}{}|0,\mp@subsup{F}{i}{})
    return }\operatorname{log}p(v,0,Y
```

## C. 2 Variational Inference Objective

In section 3.3, we introduced a novel algorithm to perform variational inference in GMRF models using a precision parameterised Gaussian variational distribution. Algorithm 7 provides some details of how we use our operators for banded matrices to evaluate the variational lower bound to the marginal likelihood.

```
Algorithm 7 Variational Inference objective evaluation.
Input : prior parameters:
    \(m_{p}\) : vector of length \(n\)
    \(L_{p}: n \times n\) lower triangular matrix with \(l_{p}\) sub-diagonals
    variational parameters:
    \(m_{q}\) : vector of length \(n\)
    \(L_{q}: n \times n\) lower triangular matrix with \(l_{q}\) sub-diagonals
    observations \(Y\) : vector of length \(n\)
Output: variational objective \(\mathcal{L}\)
    \% Compute marginal variance
    \(\sigma_{F}^{2} \leftarrow \operatorname{diag}\left[\mathbb{I}\left(L_{F}\right)\right]\).
    \% Evaluate KL divergence
    \(K L \leftarrow \frac{1}{2}\left(\operatorname{tr}\left(\mathbb{I}\left(L_{q}\right) \mathbb{P}\left(L_{p}, L_{p}^{T}\right)\right)+2 \sum_{i}\left(\log \left[L_{q}\right]_{i i}-\log \left[L_{p}\right]_{i i}\right)+\left\|\mathbb{P}\left(L_{p}^{T}, m_{p}-m_{q}\right)\right\|^{2}-n\right)\)
    \% Evaluate variational expectations
    \(V E \leftarrow \sum_{i=1}^{n} \mathbb{E}_{q\left(F_{i}\right)=\mathcal{N}\left(\mu_{F, i}, \sigma_{F, i}^{2}\right.} \log p\left(Y_{i} \mid F_{i}\right)\)
    \% Return variational lower bound
    \(\mathcal{L} \leftarrow V E-K L\)
    return \(\mathcal{L}\)
```

## C. 3 Marginal Likelihood

In section 3.1, we explained how to efficiently compute marginal likelihood compuation in conjugate GMRFs with partial observations. In Algorithm 8, we give further details about how we use our operators for banded matrices to achieve these efficient compuations.

Nicolas Durrande, Vincent Adam, Lucas Bordeaux, Stefanos Eleftheriadis and James Hensman

The generative model is the following: latent vector $f$ has a zero mean multivariate Gaussian prior with precision $Q$, observation model is additive white noise with variance $\tau^{2}$.

```
Algorithm 8 Marginal Likelihood
Input : parameter \(\theta\)
    prior precision \(Q: n \times n\) symmetric matrix with \(l\) sub-diagonals
    observations \(Y\) : vector of length \(n\)
    indicator matrix \(E\) : matrix of size \(n \times N\)
Output: \(\log p(Y \mid \theta)\)
    \% Cholesky factorization of the posterior precision
    \(L \leftarrow \mathbb{C}\left(Q+\tau^{-2} E^{T} E\right) \%\) note that \(E^{T} E\) is diagonal
    \% Cholesky factorization of the prior precision
    \(L^{\prime} \leftarrow \mathbb{C}(Q)\)
    \% Evaluation of the Marginal likelihood
    \(R \leftarrow S\left(L, E^{T} Y\right)\)
    \(\log p(Y \mid \theta) \leftarrow-\frac{n}{2} \log (2 \pi)-\log |L|+\log \left|L^{\prime}\right|-\frac{1}{2 \tau^{2}} Y^{T} Y+\frac{1}{2 \tau^{4}} R^{T} R\)
    return \(\log p(Y \mid \theta)\)
```

## C. 4 Classical Kalman filter recursions

In section 5.2, we compared our implementation of Gaussian process regression (for kernels have a state-space representation) using our operators to traditional implementations using Kalman filtering. In this section and summarized in Algorithm 9 are derivations of the classic Kalman filter recursions.

We implement the filtering recursions for a linear state-space model with state dimension $d$ and observation dimension $e$ defined as

$$
F_{t} \sim \mathcal{N}\left(F_{t} ; A_{t} F_{t-1}+b_{t} ; Q_{t}\right), \quad Y_{t} \sim \mathcal{N}\left(Y_{t} ; H F_{t}+c, R\right)
$$

with $F_{0} \sim \mathcal{N}\left(F_{0} ; \mu_{0}, \Sigma_{0}\right)$. For a sequence of $T$ observations stacked into $Y^{T}=\left[Y_{1}^{T}, \ldots, Y_{T}^{T}\right] \in \mathbb{R}^{T e}$, the aim is to evaluate $p(Y)$ which can be expressed in terms of conditionals densities $p(Y)=\prod_{t} p\left(Y_{t} \mid Y_{1 \ldots t-1}\right)$. These conditional densities can be obtained after one pass of the Kalman filtering recursions as follows:

Define $p\left(F_{t} \mid Y_{1 \ldots t-1}\right)=\mathcal{N}\left(F_{t} ; \mu_{t}, \Sigma_{t}\right)$. We update the belief on $F_{t}$ after observing $Y_{t}$ :

$$
\begin{aligned}
p\left(F_{t} \mid Y_{1 \ldots t}\right) & =p\left(F_{t} \mid Y_{1 \ldots t-1}, Y_{t}\right) \\
& \propto p\left(Y_{t} \mid F_{t}, Y_{1 \ldots t-1}\right) p\left(F_{t} \mid Y_{1 \ldots t-1}\right) \\
& \propto p\left(Y_{t} \mid F_{t}\right) p\left(F_{t} \mid Y_{1 \ldots t-1}\right) \\
& =\mathcal{N}\left(F_{t} ; \bar{\mu}_{t}, \bar{\Sigma}_{t}\right)
\end{aligned}
$$

with

$$
\begin{aligned}
\bar{\Sigma}_{t} & =\left(\Sigma_{t}^{-1}+H^{T} R^{-1} H\right)^{-1} \\
& =\Sigma_{t}-\Sigma_{t} H^{T}\left(R+H \Sigma_{t} H^{T}\right)^{-1} H \Sigma_{t} \\
& =\left(I-K_{t} H\right) \Sigma_{t}, \quad K_{t}=\Sigma_{t} H^{T}\left(R+H \Sigma_{t} H^{T}\right)^{-1} \\
\bar{\mu}_{t} & =\bar{\Sigma}_{t}\left(\Sigma_{t}^{-1} \mu_{t}+H^{T} R^{-1}\left(Y_{t}-c\right)\right) \\
& =\left(I-K_{t} H\right) \mu_{t}+K_{t}\left(Y_{t}-c\right)
\end{aligned}
$$

$K_{t}$ corresponds to the Kalman gain. Then we predict one step ahead:

$$
\begin{aligned}
p\left(F_{t+1} \mid Y_{1 \ldots t}\right) & =\int d F_{t} p\left(F_{t+1} \mid F_{t}\right) p\left(F_{t} \mid Y_{1 \ldots t}\right) \\
& =\mathcal{N}\left(F_{t} ; \mu_{t+1}, \Sigma_{t+1}\right)
\end{aligned}
$$

SO

$$
\begin{aligned}
\Sigma_{t+1} & =A_{t+1} \bar{\Sigma}_{t} A_{t+1}^{T}+Q_{t+1} \\
\mu_{t+1} & =A_{t+1} \bar{\mu}_{t}+b_{t+1}
\end{aligned}
$$

In the end, for the marginal likelihood computation, we need:

$$
\begin{aligned}
p\left(Y_{t} \mid Y_{1 \ldots t-1}\right) & =\int d F_{t} p\left(Y_{t} \mid F_{t}\right) p\left(F_{t} \mid Y_{1 \ldots t-1}\right) \\
& =\mathcal{N}\left(Y_{t} ; H \mu_{t}, H \Sigma_{t} H^{T}+R\right)
\end{aligned}
$$

```
Algorithm 9 Kalman Filtering
Input : parameters \(\theta=\left[A_{t}, b_{t}, Q_{t}, H, c, R\right]\), Observations \(Y\)
Output: \(\log p(Y \mid \theta)\)
    \(L \leftarrow 0\)
    for \(t=1 \ldots T\) do
        \% incorporation of observation \(Y_{t}\)
        \(K_{t} \leftarrow \Sigma_{t} H^{T}\left(R+H \Sigma_{t} H^{T}\right)^{-1}\)
        \(\bar{\Sigma}_{t} \leftarrow\left(I-K_{t} H\right) \Sigma_{t}\)
        \(\bar{\mu}_{t} \leftarrow\left(I-K_{t} H\right) \mu_{t}+K_{t}\left(Y_{t}-c\right)\)
        \% prediction one step ahead
        \(\Sigma_{t+1} \leftarrow A_{t+1} \bar{\Sigma}_{t} A_{t+1}^{T}+Q_{t+1}\)
        \(\mu_{t+1} \leftarrow A_{t+1} \bar{\mu}_{t}+b_{t+1}\)
        \(\%\) evaluation of the log conditional \(\log p\left(Y_{t} \mid Y_{1 \ldots t-1}\right)\)
        \(L \leftarrow L+\log \mathcal{N}\left(Y_{t} ; H \mu_{t}, H \Sigma_{t} H^{T}+R\right)\)
    end for
    return \(L\)
```

## C. 5 Gaussian process regressiong with banded precision

Our implementation of Gaussian process regression, for the experiment of section 5.2, treats the chain of latent states $F^{T}=\left[F_{0}^{T}, \ldots, F_{T}^{T}\right] \in \mathbb{R}^{(T+1) d}$ and observations $Y^{T}=\left[Y_{1}^{T}, \ldots, Y_{T}^{T}\right] \in \mathbb{R}^{T e}$ as a big multivariate normal distribution $p(Y, F)$ that factorises into a prior and a likelihood as $p(Y, F)=p(Y \mid F) p(F)$. Both terms can be seen as multivariate normal densities on $F$, albeit a possibly degenerate one for $p(Y \mid F)$. They can be expressed in terms of their natural parameters:

$$
\begin{aligned}
p(F) & =\mathcal{N}\left(F ; \eta_{0}, \Lambda_{0}\right) \\
p(Y \mid F) & =\mathcal{N}\left(F ; \eta_{1}, \Lambda_{1}\right)
\end{aligned}
$$

where only $\eta_{1}$ depends on the data $Y$.
The density of a multivariate normal distribution with natural parameterisation $\eta, \Lambda$ is:

$$
\begin{aligned}
\mathcal{N}(F ; \eta, \Lambda) & =\exp \left(a(\eta, \Lambda)+\eta^{T} F+\frac{1}{2} F^{T} \Lambda F\right) \\
a(\eta, \Lambda) & =-\frac{1}{2}\left(-\log |\Lambda|+T d \log 2 \pi+\eta^{T} \Lambda^{-1} \eta\right)
\end{aligned}
$$

Hence the joint over latent $F$ and observations $Y$ is

$$
\begin{aligned}
p(F, Y) & =\mathcal{N}\left(F, \eta_{0}, \Lambda_{0}\right) \mathcal{N}\left(F, \eta_{1}, \Lambda_{1}\right) \\
& =\exp \left(a\left(\Lambda_{0}, \eta_{0}\right)+a\left(\Lambda_{1}, \eta_{1}\right)-a\left(\Lambda_{2}, \eta_{2}\right)\right) \mathcal{N}\left(F ; \eta_{2}, \Lambda_{2}\right)
\end{aligned}
$$

with $\left(\eta_{2}, \Lambda_{2}\right)=\left(\eta_{0}, \Lambda_{0}\right)+\left(\eta_{1}, \Lambda_{1}\right)$ the parameters of the Gaussian posterior on $F$.

Marginalizing over $F$ provides the log marginal

$$
\log p(Y)=a\left(\Lambda_{0}, \eta_{0}\right)+a\left(\Lambda_{1}, \eta_{1}\right)-a\left(\Lambda_{2}, \eta_{2}\right)
$$

Due to the structure of the model, the prior and likelihood terms can be further simplified:
Since $p(F)=p\left(F_{0}\right) \prod_{t} p\left(F_{t} \mid F_{t-1}\right)$, we have $\left|\Lambda_{0}\right|=\left|\Sigma_{0}\right|^{-1} \Pi_{t}\left|Q_{t}\right|^{-1}$.
Since $p(Y \mid F)=\prod_{t} p\left(Y_{t} \mid F_{t}\right)$ and noting $p\left(Y_{t} \mid F_{t}\right)=\mathcal{N}\left(F_{t} ; u_{t}, R\right)$, we have $\left|\Lambda_{1}\right|=|R|^{-T}$ and $\eta_{1}^{T} \Lambda_{1}^{-1} \eta_{1}=\sum_{t} u_{t}^{T} R u_{t}$.
All the other $\log$ determinants and quadratic terms are expressed from the Cholesky factor $C_{j}$ of $\Lambda_{j}$ as $\log \left|\Lambda_{j}\right|=$ $2 \log \left|C_{j}\right|=2 \sum_{i} \log \left[C_{j}\right]_{i i}$ and $\eta_{j}^{T} \Lambda_{j}^{-1} \eta_{j}=\left\|C_{j}^{-1} \eta_{j}\right\|^{2}$.
So we can rewrite the likelihood as

$$
\begin{aligned}
\log p(Y) & =\frac{1}{2}\left(T d \log 2 \pi-\log \left|\Sigma_{0} R^{T} \Pi_{t} Q_{t}\right|+2 \log \left|C_{2}\right|\right) \\
& +\frac{1}{2}\left(\left\|C_{0}^{-1} \eta_{0}\right\|^{2}+\sum_{t} u_{t}^{T} R u_{t}-\left\|C_{2}^{-1} \eta_{2}\right\|^{2}\right)
\end{aligned}
$$

```
Algorithm 10 Gaussian process regression (using banded matrices)
Input : parameters \(\theta=\left[A_{1 \ldots T}, b, Q_{1 \ldots T}, H, c, R\right]\),
    observation \(Y\) : vector of length \(n\)
Output: \(\log p(Y \mid \theta)\)
    \% building the prior and likelihood natural parameters [see Grigorievskiy et al 2017]
    \(\eta_{0}, \Lambda_{0} \leftarrow f\left(A_{1 \ldots T}, b, Q_{1 \ldots T}\right)\)
    \(\eta_{1}, \Lambda_{1} \leftarrow g(H, c, R, Y)\)
    \% Cholesky factorization of the prior and posterior precisions
    \(C_{0} \leftarrow \mathbb{C}\left(\Lambda_{0}\right)\)
    \(C_{2} \leftarrow \mathbb{C}\left(\Lambda_{0}+\Lambda_{1}\right)\)
    \(\%\) evaluation of the log-likelihood
    \(\log p(Y) \leftarrow \frac{1}{2}\left(T d \log 2 \pi-\log \left|\Sigma_{0} R^{T} \Pi_{t} Q_{t}\right|-2 \log \left|C_{2}\right|+\left\|C_{0}^{-1} \eta_{0}\right\|^{2}+\sum_{t} u_{t}^{T} R u_{t}-\left\|C_{2}^{-1} \eta_{2}\right\|^{2}\right)\)
    return \(L\)
```

The bottleneck in computational terms is the Cholesky factorization which scales as $O\left(T l^{3}\right)$, because $\Lambda_{\text {post }}$ is a banded precision of length $T l$ and bandwidth $2 l$.

## C. 6 Gaussian process regression

In section 5.2, we compare different implementations of Gaussian process regression to the naive one that builds a dense covariance matrix $K$ for the latent. For this latter case, the marginal likelihood is evaluated as:

$$
\log p(Y \mid \theta)=-\frac{1}{2} Y^{T}\left(K+\sigma^{2} I\right)^{-1} Y-\frac{1}{2} \log \left|K+\sigma^{2} I\right|-\frac{N}{2} \log 2 \pi
$$

Algorithm 11 provides details on how we implemented it in practice.

```
Algorithm 11 Gaussian process regression Likelihood
Input : parameter \(\theta\)
    observation \(Y\) : vector of length \(n\)
Output: \(\log p(Y \mid \theta)\)
    \% Cholesky factorization of the posterior covariance
    \(L \leftarrow \operatorname{Cholesky}\left(K+\sigma^{2} I\right)\)
    \% marginal likelihood evaluation
    \(\log p(Y \mid \theta) \leftarrow-\frac{1}{2}| | L^{-1} Y \|^{2}-\sum_{i} \log \left|L_{i i}\right|-\frac{N}{2} \log 2 \pi\)
    return \(\log p(Y \mid \theta)\)
```
