Generalized Majorization-Minimization
Supplementary Material

Sobhan Naderi 1 Kun He 2 Reza Aghajani 3 Stan Sclaroff 4 Pedro Felzenszwalb 5

In this supplementary material we will provide proofs for the two theorems that we presented in the main paper. We also provide more visualization of the models trained with G-MM and compare them with CCCP and EM, which we had to omit from the main paper due to space limitations.

1. Proof of Convergence

Proof of Theorem 1. First, we observe that the following inequality follows from the bound construction assumptions:

\[ b_t(w_t) \leq b_t(w_{t-1}) \leq v_{t-1}, \quad (14) \]

where \( v_t = b_t(w_t) - \eta d_t \). In particular, the first inequality holds because \( w_t \) minimizes \( b_t \) and the second inequality follows from (3). Summing (14) over \( t = 1, \ldots, T \) and substituting the definition of \( v_t \) gives

\[
\sum_{t=1}^{T} b_t(w_t) \leq \sum_{t=1}^{T} v_{t-1} = v_0 + \sum_{t=1}^{T-1} (b_t(w_t) - \eta d_t)
\]

which implies

\[ \eta \sum_{t=1}^{T} d_t \leq v_0 - b_T(w_T). \quad (15) \]

Recall that we set \( v_0 = F(w_0) \), and let \( F_\ast \in \mathbb{R} \) denote a finite global lower bound for \( F \), and hence \( b_T(w_T) \geq F_\ast \). The bound (15) then implies

\[ \eta \sum_{t=1}^{\infty} d_t \leq F(w_0) - F_\ast < \infty, \]

which gives \( \lim_{t \to \infty} d_t = 0 \).

Next, recall that for every \( m \)-strongly convex function \( f \), every \( x, y \) in the domain of \( f \), and every subgradient \( g \in \partial f(x) \), we have

\[ f(y) \geq f(x) + g^T(y - x) + \frac{m}{2}||x - y||^2. \quad (16) \]

Substituting \( f = b_t, x = w_t, \) and \( y = w_t - 1 \) in (16), and noting that the zero vector is a subgradient of \( b_t \) at \( w_t \) because \( w_t \) is a minimizer of \( b_t \), we obtain

\[
||w_t - w_{t-1}||^2 \leq \frac{2}{m} (b_t(w_{t-1}) - b_t(w_t)) \leq \frac{2}{m} (b_t(w_{t-1}) - b_t(w_t)), \quad (17)
\]

where (3) is used in the second inequality. Summing (17) over \( t = 1, \ldots, T \), we obtain

\[
\sum_{t=1}^{T} ||w_t - w_{t-1}||^2 \leq b_1(w_1) - b_T(w_T)
\]

\[ \leq F(w_1) - F_\ast, \quad (18) \]

which implies

\[ \lim_{t \to \infty} ||w_t - w_{t-1}|| = 0 \quad (19) \]

On the other hand, since \( F(w_1) \leq b_1(w_1) \leq F(w_0) \) by (2), the sequence \( \{w_t\} \) lies in the sublevel set \( \{w \in \mathbb{R}^n \mid F(w) \leq F(w_0)\} \), which is assumed to be a compact set. To show that a sequence that is contained in a compact set converges, one needs to prove that all its converging subsequences have the same limit. For \( \{w_t\}_t \), this follows from (19), and therefore \( \{w_t\}_t \) converges to a limit \( w^\ast \). \( \square \)

Proof of Theorem 2. We prove this theorem by contradiction. Suppose \( \nabla F(w^\ast) \neq 0 \). This implies that there exists a unit vector \( u \in \mathbb{R}^d \) such that the directional derivative of \( F \) along \( u \) is positive at \( w^\ast \), i.e. \( \nabla F(w^\ast) \cdot u > 2c \) for some \( c > 0 \). Since \( F \) is continuously differentiable, \( \nabla F \cdot u \) is continuous at \( w^\ast \), and hence

\[ \nabla F(w) \cdot u > c, \quad \forall w \in B_{2\delta}(w^\ast), \quad (20) \]

for all small enough \( \delta > 0 \), where \( B_r(x) \) denotes an open ball around \( x \) with radius \( r \). We fix a \( \delta > 0 \) that satisfies (20), as well as the bound

\[ \delta < \frac{2c}{M}. \quad (21) \]

\[ \]
We also fix an $\epsilon > 0$ that satisfies
\[ \epsilon < c\delta - \frac{M}{2}\delta^2, \tag{22} \]
which is possible because of (21). The reason for this will be clear shortly.

Now recall by Theorem 1 that $w_t \to w^\dagger$ and $d_t \to 0$, as $t \to \infty$, so we can pick $T > 0$ large enough such that
\[ |w_T - w^\dagger| < \delta \tag{23} \]
and
\[ d_T = b(w_T) - F(w_t) < \epsilon \tag{24} \]
Now define the function $g$ to be the restriction of $F$ on a line parallel to $u$ that passes through $w_T$ (see Figure 1), that is
\[ g(z) = F(w_T + zu), \quad z \in \mathbb{R}. \]
It is easy to see that $g$ is continuously differentiable with
\[ g'(z) = \nabla F(w_T + zu) \cdot u. \]
In particular, the bound (20) implies
\[ g'(z) > c, \quad z \in (0, \delta). \tag{25} \]
This is because for every $z \in (0, \delta)$,
\[ w_T + zu \in B_\delta(w_T) \subset B_{2\delta}(w^\dagger). \]
An application of Taylor Expansion Theorem of order $n = 0$ on $g$ around $z = 0$ shows that there exits a $z_* \in (0, \delta)$ such that
\[ g(\delta) = g(0) + g'(z_*)\delta > g(0) + c\delta, \]
where we used $g'(z_*) > c$ by (25). Substituting definitions of $g(0)$ and $g'(0)$ in the display above, we obtain the bound
\[ F(w_*) > F(w_T) + c\delta, \quad w_* = w_T + \delta u. \tag{26} \]

On the other hand, since $b_T$ is a smooth function with its minimum at $w_T$ and its Hessian $\nabla^2 b_T$ bounded by $MI$, second order Taylor expansion of $b_T$ around $w_T$ gives
\[ b_T(w) \leq b_T(w_T) + \nabla b_T(w_T) \cdot (w - w_T) + \frac{M}{2} \|w - w_T\|^2, \]
and in particular, for $w = w_* = w_T + \delta u$,
\[ b_T(w_*) \leq b_T(w_T) + \frac{M}{2}\delta^2. \tag{27} \]
Combining the bounds (24)-(27) and the choice (22) of $\epsilon$, we have
\[ b_T(w_*) - F(w_*) \leq \left[ b_T(w_T) - F(w_T) \right] + \frac{M}{2}\delta^2 - c\delta \leq \epsilon + \frac{M}{2}\delta^2 - c\delta < 0, \]
which contradicts the fact that $b_T$ is an upper bound for $F$. This completes the proof. \hfill \Box

2. $k$-means Clustering

Figure 2 visualizes the result of $k$-means and G-MM (with random bounds) on the D-31 dataset (Veenman et al., 2002), from the same initialization. G-MM finds a near perfect solution, while in standard $k$-means, many clusters get merged incorrectly or die off. Dead clusters are those which do not get any points assigned to them. The update rule (M-step of $k$-means algorithm) collapses the dead clusters on to the origin.

3. LS-SVM for Mammal Image Classification

We provide additional experimental results on the mammals dataset. Figure 3 shows example training images and the final imputed latent object locations by three algorithms: CCCP (red), G-MM random (blue), and G-MM biased (green). The initialization is top-left.

In most cases CCCP fails to update the latent locations given by initialization. The two G-MM variants, however, are able to update them significantly and often localize the objects in training images correctly. This is achieved only with image-level object category annotations, and with a very bad (even adversarial) initialization.

References

Figure 2. Visualization of clustering solutions on the D31 dataset (Veenman et al., 2002) from identical initializations. Random partition initialization scheme is used. (a) color-coded ground-truth clusters. (b) solution of $k$-means. (c) solution of G-MM. The white crosses indicate location of the cluster centers. Color codes match up to a permutation.
