Nearly Optimal Competitive Ratio for Online Allocation Problems with Two-sided Resource Constraints and Finite Requests

Qixin Zhang 1 2 Wenbing Ye 2 Zaiyi Chen 2 Haoyuan Hu 2 Enhong Chen 3 Yu Yang 1

Abstract

In this paper, we investigate the online allocation problem of maximizing the overall revenue subject to both lower and upper bound constraints. Compared to the extensively studied online problems with only resource upper bounds, the two-sided constraints affect the prospects of resource consumption more severely. As a result, only limited violations of constraints or pessimistic competitive bounds could be guaranteed. To tackle the challenge, we define a measure of feasibility $\xi^*$ to evaluate the hardness of this problem, and estimate this measurement by an optimization routine with theoretical guarantees. We propose an online algorithm adopting a constructive framework, where we initialize a threshold price vector using the estimation, then dynamically update the price vector and use it for decision-making at each step. It can be shown that the proposed algorithm is $(1 - O(\frac{1}{\sqrt{\xi^*}}))$ or $(1 - O(\frac{1}{\sqrt{\xi^*}T}))$ competitive with high probability for $\xi^*$ known or unknown respectively. To the best of our knowledge, this is the first result establishing a nearly optimal competitive algorithm for solving two-sided constrained online allocation problems with a high probability of feasibility.

1. Introduction

Online resource allocation is a prominent paradigm for sequential decision making during a finite horizon subject to the resource constraints, increasingly attracting the wide attention of researchers and practitioners in theoretical computer science (Mehta et al., 2007; Devanur & Jain, 2012; Devanur et al., 2019), operations research (Agrawal et al., 2014), computer science (Mehta et al., 2007; Devanur & Jain, 2012; De-
The goal is to maximize the total revenue subject to the two-sided resource constraints. In the beginning, the decision maker is endowed with a limited and unreplenishable amount of resources, and agrees a minimum consumption on each resource. The decision maker can access the information of the current request and requests that have been processed before, but it is unable to get the information of future requests until their arrivals. Once observing an online request, the decision is made irrevocably to assign one available channel to serve the request, where we assume there is an oracle that determines the revenue and the amount of consumed resources depending on (request, channel) pair for convenience. A formal definition can be found in Section 3.

To address the challenges brought by two-sided resource constraints, we first define a problem dependent quantity \( \gamma \) to represent i) the maximum fraction of revenue or resource consumption per request, ii) the pessimism about the satisfaction of lower bound constraints. Generally, large \( \gamma \) will rule out good competitive ratio across different settings (Mehta et al., 2007; Buchbinder et al., 2007; Agrawal et al., 2014; Devanur et al., 2019). Meanwhile, we find that the margins between lower and upper bounds directly affect the hardness of the online allocation problem in stochastic setting. Inspired by the Slater’s condition and its applications (Slater, 2014; Boyd et al., 2004), we define a measure of feasibility \( \xi^* \) to evaluate the hardness of constraints and present an estimator with sufficient accuracy. In the end, the proposed algorithm integrates several estimators to compensate undiscovered information. Our contribution can be summarized as follows:

1. Under the gradually improved assumptions, we propose three algorithms that return \( 1 - O(\frac{\varepsilon}{\xi - \varepsilon}) \) competitive solutions satisfying the two-sided constraints w.h.p., if \( \gamma \) is at most \( O\left(\frac{\varepsilon^2}{\ln(K/\varepsilon)}\right) \), where \( \xi^* \gg \varepsilon \) is the measure of feasibility and \( K \) is the number of resources. To the best of our knowledge, this is the first result establishing a competitive algorithm for solving two-sided constrained online allocation problems feasibly, which is nearly optimal according to (Devanur et al., 2019).
2. To tackle the unknown parameter \( \xi^* \), we propose an optimization routine in Algorithm 3. Through merging the estimate method into the previous framework, a new algorithm is proposed in Algorithm 4 with a solution achieving \( 1 - O(\frac{\varepsilon}{\xi - \sqrt{\varepsilon}}) \) competitive ratio when \( \xi^* \) is an unknown and problem dependent constant.
3. Our analytical tools can be used to strengthen the existing models (Mehta et al., 2007; Devanur et al., 2019; Lobos et al., 2021) for online resource allocation problems.

2. Related Works

Online allocation problems have been extensively studied in theoretical computer science and operations research communities. In this section, we overview the related literature.

When the incoming requests are adversarially chosen, there is a stream of literature investigating online allocation problems. Mehta et al. (2007) and Buchbinder et al. (2007) first study the AdWords problem, a special case of online allocation, and provide an algorithm that obtains a \((1 - 1/e)\) approximation to the offline optimal allocation, which is optimal under the adversarial input model. However, the adversarial assumption may be too pessimistic about the requests. To consider another application scenarios, Devanur & Hayes (2009) propose the random permutation model, where an adversary first selects a sequence of requests which are then presented to the decision maker in random order. This model is more general than the stochastic i.i.d. setting in which requests are drawn independently and at random from an unknown distribution. In this new stochastic model, Devanur & Hayes (2009) revisit the AdWords problem and present a dual training algorithm with two phases: a training phase where data is used to estimate the dual variables by solving a linear program and an exploitation phase where actions are taken using the estimated dual variables. Their algorithm is guaranteed to obtain a \( 1 - o(1) \) competitive ratio, which is problem dependent. Feldman et al. (2010) show that this training-based algorithm could resolve more general linear online allocation problems. Pushing these ideas one step further, Agrawal et al. (2014) consider primal and dual algorithm that dynamically updates dual variables by periodically solving a linear program using the data collected so far. Meanwhile, Kesselheim et al. (2014) take the same policy and only consider renewing the primal variables. Recently, Devanur et al. (2019) take other innovative techniques to geometrically update the price vector via some decreasing potential function derived from probability inequalities. These algorithms also obtain \( 1 - o(1) \) approximation guarantees under some mild assumptions. While the algorithms described above usually require solving large linear problems periodically, there is a recent line of work seeking simple algorithms that does not need to solve a large linear programming. Balseiro et al. (2020) study a simple dual mirror descent algorithm for online allocation problems with concave reward functions and stochastic inputs, which attains \( O(\sqrt{KT}) \) regret, where \( K \) and \( T \) are the number of resources and requests respectively, i.e., updating dual variables via mirror descent algorithm and avoids solving large auxiliary linear programming. Simultaneously, Li et al. (2020) present a similar fast algorithm that updates the dual variable via projected gradient descent in every round for linear rewards. It is worth noting that all of these literature only consider the online allocation with capacity constraints.
3. Preliminaries and Assumptions

In this section, we introduce some essential concepts and assumptions that are adopted in our framework.

3.1. Two-sided Resource Allocation Framework

We consider the following framework for offline resource allocation problems. Let $\mathcal{K}$ be the set of $|\mathcal{K}|$ kinds of resources. There are $\mathcal{J}$ different types of requests. Each request $j \in \mathcal{J}$ could be served via some channel $i \in \mathcal{I}$, which will consume $a_{ijk}$ amount of resource $k \in \mathcal{K}$ and generate $w_{ij}$ amount of revenue. For each resource $k \in \mathcal{K}$, $L_k$ and $U_k$ denote the lower bound requirement and capacity, respectively. The objective of the two-sided resource allocation is to maximize the revenue subject to the two-sided resource constraints. The following is the offline integer linear programming for resource allocation where the entire sequence of $T$ requests is given in advance:

$$W_R = \max_x \sum_{i \in \mathcal{I}, t \in [T]} w_{i}R(t)x_{it}$$

s.t. $L_k \leq \sum_{i \in \mathcal{I}, t \in [T]} a_{iR(t), t}x_{it} \leq U_k, \forall k \in \mathcal{K}$

$$\sum_{i \in \mathcal{I}} x_{it} \leq 1, \forall t \in [T]$$

$$x_{it} \in \{0, 1\}, \forall i \in \mathcal{I}, t \in [T]$$

where $[T] = \{1, 2, \ldots, T\}$ and the function $R(t) : [T] \rightarrow \mathcal{J}$ to record the types of requests, i.e., the type of $t$-th request is $R(t)$. As a common relaxation in online resource allocation literature (Agrawal et al., 2014; Devanur et al., 2019; Li et al., 2020; Balseiro et al., 2020), not picking any channel is permitted in ILP (1). We denote the no picking channel option by $\bot \in \mathcal{I}$, where $a_{\bot ik} = 0$ and $w_{i\bot} = 0$ for all $j \in \mathcal{J}$ and $k \in \mathcal{K}$.

3.2. Assumptions and Concepts

To facilitate the analysis in following sections, we hereby explain the detailed assumptions for two-sided online resource allocation problem.

In practice, it’s impossible to know all incoming requests ahead of time. We therefore assume:

**Assumption 1.** The requests arrive sequentially and are independently drawn from some unknown distribution $P : \mathcal{J} \rightarrow [0, 1]$ where $P(j)$ denotes the arrival probability of request $j \in \mathcal{J}$ and we denote $p_j = P(j), \forall j \in \mathcal{J}$.

To demonstrate the performance of our proposed algorithms, we also need to make some extra requirements about the parameters, which are widely adopted in literature.

**Assumption 2.** In stochastic settings, we make the following reasonable assumptions:

i. When the algorithm is initialized, we know the lower and upper bound requirements $L_k$ and $U_k$ regarding every resource $k \in \mathcal{K}$ and the number of requests $T$.

ii. Without loss of generality, the revenues $w_{ij}$ and consumption of resources $a_{ijk}$ are finite, non-negative and revealed when each request arrives, \(\forall i \in \mathcal{I}, j \in \mathcal{J}, k \in \mathcal{K}\). Moreover, we know $\bar{w} = \sup_{i \in \mathcal{I}, j \in \mathcal{J}} w_{ij}$ and $\bar{a}_k = \sup_{i \in \mathcal{I}, j \in \mathcal{J}} a_{ijk}, \forall k \in \mathcal{K}$.

Under Assumption 1 and 2 we denote the expected Linear Programming problem with lower bound $L_k + \beta T\bar{a}_k$ for every resource $k \in \mathcal{K}$ by $E(\beta)$, i.e.,

$$W_\beta = \max_x \sum_{i \in \mathcal{I}, j \in \mathcal{J}} T p_j w_{ij} x_{ij}$$

s.t. $L_k + \beta T\bar{a}_k \leq \sum_{i \in \mathcal{I}, j \in \mathcal{J}} T p_j a_{ijk} x_{ij} \leq U_k, \forall k \in \mathcal{K}$

$$\sum_{i \in \mathcal{I}} x_{ij} \leq 1, \forall j \in \mathcal{J}$$

$$x_{ij} \geq 0, \forall i \in \mathcal{I}, j \in \mathcal{J}$$

where $\beta$ is a deviation parameter of lower bound constraints and $W_\beta$ is the optimal value for problem $E(\beta)$. Meanwhile, we denote the optimal solution for $E(\beta)$ as $\{x(\beta)_{ij}, \forall i \in \mathcal{I}, j \in \mathcal{J}\}$. Under Assumption 1 if we take the same policy for every request $j \in \mathcal{J}$ in ILP (1), i.e., $x_{it} = x(\beta)_{ij}^* \forall i \in \mathcal{I}, t \in [T]$ when $R(t) = j$, it can be verified that $E\left[\sum_{i \in \mathcal{I}, j \in \mathcal{J}} a_{iR(t), t} x_{it}\right] = \sum_{i \in \mathcal{I}, t \in [T]} T p_j a_{ijk} x(\beta)_{ij}^*$ and $E\left[\sum_{i \in \mathcal{I}, t \in [T]} w_{iR(t), t}\right] = \sum_{i \in \mathcal{I}, t \in [T]} T p_j w_{ij} x(\beta)_{ij}^*$. Therefore, when $\beta = 0$, we could view the LP (2) as a relaxed version of the expectation of ILP (1). Moreover, $W_0$ is an upper bound of the expectation of the optimal reward $W_R$ in ILP (1).

**Lemma 3.1.** $W_0 \geq E[W_R]$.

The proof of the above lemma is deferred to Appendix [C]. As a result, if an algorithm attains $(1 - o(1)) W_0$, we can infer that this algorithm also achieves at least $(1 - o(1)) E[W_R]$.

We also make an assumption on the margin of resource constraints.

**Assumption 3.** (Strong feasible condition)

There exists a $\xi > 0$ making the linear constraints of the following problem feasible,

$$\xi^* = \max_{\xi \geq 0} \xi$$

s.t. $L_k + \xi T \bar{a}_k \leq \sum_{i \in \mathcal{I}, j \in \mathcal{J}} T p_j a_{ijk} x_{ij} \leq U_k, \forall k \in \mathcal{K}$

$$\sum_{i \in \mathcal{I}} x_{ij} \leq 1, \forall j \in \mathcal{J}$$

$$x_{ij} \geq 0, \forall i \in \mathcal{I}, j \in \mathcal{J}$$

(3)
The motivation for adding $\xi T \bar{a}_k$ to the lower bound is to measure the size of the original feasible space with lower bound $L_k$ and upper bound $U_k$. Intuitively, it is relatively easy to satisfy the lower-bound requirements in the wide feasible space at the end of $T$-round decisions. Therefore, we call the optimal $\xi^*$ the measure of feasibility and assume $\xi^* \gg \varepsilon$ for simplicity, where $\varepsilon > 0$ is a predefined error parameter.

Due to limited space, we present some frequently used concentration inequalities to predigest the theoretical analysis in Appendix B.

4. Competitive Algorithms for Online Resource Allocation with Two-sided Constraints

In this section, we propose a series of online algorithms for resource allocation with two-sided constraints by progressively weakening the following assumptions.

4.1 and 4.2. With known distribution;
4.3. With known optimal objective;
4.4. Completely unknown distribution.

4.1. With Known Distribution

In this section, we assume that we have the complete knowledge of the distribution $\mathcal{P}$. We first propose a high-level overview of our algorithm and outcomes as follows.

High-level Overview:

1. With the knowledge of $\mathcal{P}$, we could directly solve the expected problem $E(\tau)$ and obtain the optimal solution $\{x(\tau)^*_i\}_{i \in \mathcal{I}, j \in \mathcal{J}}$, where the deviation parameter $\tau = \frac{1}{1 - \gamma}$. For each fixed request $j \in \mathcal{J}$, if $x(\tau)^*_i \geq x(\tau)^*_i$, we tend to assign this type of request to channel $i_1$ rather than $i_2$. Motivated by this intuition, we design the Algorithm $\bar{P}$ in Algorithm 1 which assigns request $j \in \mathcal{J}$ to channel $i \in \mathcal{I}$ with probability $(1 - \varepsilon)x(\tau)^*_i$.

2. In the Algorithm $\bar{P}$, if we define the r.v. $X^\bar{P}_k$ for resource $k$ consumed by one request sampled from distribution $\mathcal{P}$ and r.v. $Y^\bar{P}$ for the revenue, it is easy to obtain that $(1 - \varepsilon) \frac{L_k}{T_k} + \varepsilon \bar{a}_k \leq \mathbb{E}(X^\bar{P}_k) \leq (1 - \varepsilon) \frac{U_k}{T_k}$ and $\mathbb{E}(Y^\bar{P}) = (1 - \varepsilon) \frac{\bar{W}}{T_k}$. Because the expectation of resource consumption about one sample is restricted to the interval $[\frac{L_k}{T_k}, \frac{U_k}{T_k}]$, in Theorem 4.3, we could prove that the Algorithm $\bar{P}$ generates a feasible solution with high probability for online resource problem with two-sided constraints ILP (1) via the Bernstein inequalities in Lemma B.1. This is the reason for enlarging the lower bound $L_k$ by $\tau T \bar{a}_k$ and scaling the solution with a factor $1 - \varepsilon$. Meanwhile, we also verify that the accumulative revenue will be no less than $(1 - 2\varepsilon)W_\tau$ w.p. $1 - \varepsilon$ in Lemma 4.1.

3. Since we have lifted the lower resource constraints from $L_k$ to $L_k + \tau T \bar{a}_k$ in Algorithm $\bar{P}$, it would cause the change of baseline when analyzing the accumulative revenues. We have to derive the relationship between $W_\tau$ and $W_0$. By taking a sensitive analysis in Section 4.2, we obtain $W_\tau \geq (1 - \frac{\varepsilon}{\gamma})W_0$ in Theorem 4.2 under the Assumption [1] where $\xi^*$ is the measure of feasibility. Finally, we could prove the Algorithm $\bar{P}$ achieves an objective value at least $(1 - O(\varepsilon))W_0$ in Theorem 4.3.

Similar to [Devanur et al., 2019], we first consider the competitive ratio that Algorithm $\bar{P}$ could achieve for a surrogate LP problem $E(\tau)$ with optimal objective $W_\tau$ according to Definition [3].

Lemma 4.1. Under Assumption [1], if $\forall \varepsilon > 0$ and $\gamma = \max(\frac{2}{T_k}, \frac{\bar{a}_k}{\tau L_k - L_k}, \frac{\bar{a}_k}{\bar{W}}) = O(\frac{\varepsilon^{1/3}}{\ln(1/\varepsilon)})$, Algorithm $\bar{P}$ achieves an objective value at least $(1 - 2\varepsilon)W_\tau$ and satisfies the constraints w.p. $1 - \varepsilon$.

The proof is deferred to Appendix B. From Lemma 4.1, we have verified the cumulative revenue is at least $(1 - 2\varepsilon)W_\tau$, w.p. $1 - \varepsilon$. Thus, in order to compare the revenue with $W_0$, we should derive the relationship between $W_\tau$ and $W_0$. However, due to the deviation $\tau T \bar{a}_k$, it is hard to directly obtain this relationship. We will tackle this sensitive problem in the next subsection.

4.2. Sensitive Analysis

In this subsection, we demonstrate the relationship between $W_\tau$ and $W_0$. Before introducing the details, we first notice the difference between the problem $E(\tau)$ and the problem $E(0)$. Specifically, we enlarge the lower bound for every resource $k \in \mathcal{K}$ by an extra amount of $\tau T \bar{a}_k$.

Through a sensitive analysis, we finally found that the measure of feasibility $\xi^*$ controls the decline ratio of the $E(\tau)$ objective value. The result can be summarized by follows.

Theorem 4.2. Under the strong feasible condition in As-
We prove Theorem 4.2 from a geometrical perspective.

We prove Theorem 4.2 from a geometrical perspective.

Proof. Let \( x'_{ij} = (1 - \frac{\tau}{\xi^*})x(0)_{ij}^{*} + \frac{\tau}{\xi^*}x(\xi^*)_{ij}^{*} \), \( \forall i \in \mathcal{I} \) and \( j \in \mathcal{J} \), then \( x'_{ij} \) is a convex combination between the optimal solutions of \( E(0) \) and \( E(\xi^*) \). According to the constraint set of problem \( E(0) \) and \( E(\xi) \), we can verify that \( x'_{ij} \) is non-negative and satisfies \( \sum_{i \in \mathcal{I}, j \in \mathcal{J}} T p_j a_{ijk} x'_{ij} \leq U_k \), \( \forall k \in \mathcal{K} \). \( \sum_{i \in \mathcal{I}} x_{ij} \leq 1, \forall j \in \mathcal{J} \).

Meanwhile, \( W_{r} \geq \sum_{i \in \mathcal{I}, j \in \mathcal{J}} T p_j a_{ijk} x'_{ij} \geq (1 - \frac{\tau}{\xi^*})x(0)_{ij}^{*} + \frac{\tau}{\xi^*}x(\xi^*)_{ij}^{*} \) (4)
\[ \geq (1 - \frac{\tau}{\xi^*})L_k + \frac{\tau}{\xi^*}(L_k + \xi^* T \tilde{a}_k) \]
\[ \geq L_k + \tau T \tilde{a}_k, \forall k \in \mathcal{K}. \]
Thus \( x'_{ij} \) is feasible to \( E(\tau) \), and
\[ W_{r} \geq \sum_{i \in \mathcal{I}, j \in \mathcal{J}} T p_j w_{ij} x'_{ij} \geq (1 - \frac{\tau}{\xi^*})W_0. \]
This completes the proof of Theorem 4.2.

In practical problems, the influence of \( \xi^* \) on competitive ratio may be far better than the worst case bound in Theorem 4.2, since constraints usually represent different resource requirements and only affect a part of requests. It is worth mentioning that our initial proof of Theorem 4.2 was based on analyzing a factor-revealing fractional linear programming problem motivated by Jain et al. (2003). Although the above geometric proof of Theorem 4.2 is simpler, the factor-revealing prospect tells more relationship about the dual value \( \sum_{k \in \mathcal{K}} a_k \beta_k \), \( W_0 \) and \( \xi^* \), which plays a key role in deriving Theorem 4.5 (See the end of Lemma 4.1). We put this analysis in Appendix D due to the space limit and wish to provide more insights.

Combining Lemma 4.1 with Theorem 4.2, we can show that the cumulative revenue obtained by Algorithm \( \tilde{P} \) is larger than \( (1 - 2\epsilon)W_r \geq (1 - 2\epsilon)(1 - \frac{\tau}{\xi^*})W_0 \geq (1 - (2 + \frac{1}{\xi^*})\epsilon)W_0. \) Therefore, we have the following theorem.

Theorem 4.3. Under Assumption 4.1 if \( \epsilon > 0, \tau = \frac{\epsilon}{\xi^*} \) and \( \gamma = O(\frac{\epsilon^2}{\ln(\mathcal{K}/\gamma)}) \), Algorithm \( \tilde{P} \) achieves an objective value of at least \( (1 - (2 + \frac{1}{\xi^*})\epsilon)W_0 \) and satisfies the constraints w.p. \( 1 - \epsilon \).
Nearly Optimal Competitive Ratio for Online Allocation Problems with Two-sided Resource Constraints and Finite Requests

\( M \bar{P}^{T-1} \) is bounded by \( F(M \bar{P}^{T-1}) \):
\[
F(M \bar{P}^{T-1}) = \left( \mathbb{E}\left[ \sum_{k \in \mathcal{K}} \exp\left( -\frac{\ln(1 - \epsilon)}{\bar{a}_k} \left( \frac{M_{ik}}{T} - U_k \right) \right) \right] + \sum_{k \in \mathcal{K}} \exp\left( -\frac{\ln(1 - \epsilon)}{\bar{a}_k} \left( \frac{L_k}{T} - X^{M}_{ik} \right) \right) + \exp\left( -\frac{\ln(1 - \epsilon)}{\bar{w}} \left( \frac{1 - 2\epsilon}{T} - W_i \right) \right) \right) \exp\left( -\frac{T - 1}{2} \epsilon^2 \right) \).\]

Notably, when \( M = \bar{P} \), \( F(\bar{P}^{T}) \leq (2K+1) \exp(-\frac{T^2}{2}) \leq \epsilon \) (see Appendix E). As a result, we can conclude that the best choice \( \bar{M} \) satisfies \( F(\bar{M}^{T-1}) = \min_{\bar{M}} F(M \bar{P}^{T-1}) \leq F(\bar{P}^{T}) \leq \epsilon \). Since we have finite \( J \) different types of requests, we also can show
\[
\min_{\bar{M}} F(M \bar{P}^{T-1}) = \left( \mathbb{E}\left[ \min_{i \in \mathcal{I}} \left( \sum_{k \in \mathcal{K}} \exp\left( -\frac{\ln(1 - \epsilon)}{\bar{a}_k} \left( a_{ik} - U_k \right) \right) \right) \right] + \sum_{k \in \mathcal{K}} \exp\left( -\frac{\ln(1 - \epsilon)}{\bar{a}_k} \left( \frac{L_k}{T} - a_{ik} \right) \right) + \exp\left( -\frac{\ln(1 - \epsilon)}{\bar{w}} \left( \frac{1 - 2\epsilon}{T} - w_i \right) \right) \right) \exp\left( -\frac{T - 1}{2} \epsilon^2 \right) = \left( \frac{1}{T} \right)^K (5).
\]

From line 6 in Algorithm A (Algorithm 2 and Equation 5), we could check that \( \bar{M} \) is equal to the decision of \( M \) for the first request, so \( F(A \bar{P}^{T-1}) = F(M \bar{P}^{T-1}) \leq F(\bar{P}^{T}) \leq \epsilon \). Therefore, we ensure that Algorithm \( A \bar{P}^{T-1} \) achieves an objective value at least \( (1 - O(\epsilon))W_0 \) and satisfies the constraints w.p. \( 1 - \epsilon \).

Like the previous policy, based on \( A \bar{P}^{T-1} \), we also construct another two-step hybrid algorithm \( AM \bar{P}^{T-2} \) which runs \( A \) for the first request, \( M \) for the second one and \( \bar{P} \) for the rest. Similarly, the probability of its bad events is less than some \( F(AM \bar{P}^{T-2}) \). Moreover, we know the best \( \bar{M}_1 \) satisfying \( F(AM \bar{M}_1 \bar{P}^{T-2}) \leq F(AM \bar{P}^{T-1}) \leq \epsilon \) and \( \bar{M}_1 \) is the same with the second iteration of \( A \). Continuing these iterations, we finally get a \( T \)-step hybrid method \( A^{T} \) satisfying the constraints and attaining an objective value at least \( (1 - O(\epsilon))W_0 \) w.p. \( 1 - \epsilon \). This \( A^{T} \) is in accord with all iterations of our Algorithm 2.

**Theorem 4.4.** Under Assumption 1(E) if \( \epsilon > 0, \tau \) and \( \gamma \) are defined as Theorem 4.2, the Algorithm 2 achieves an objective value at least \( (1 - (2 + \frac{1}{\epsilon^2})\epsilon)W_0 \) and satisfies the constraints w.p. \( 1 - \epsilon \).

The proof is deferred to Appendix F.

### 4.4 With Known \( \xi^* \) but Unknown Distribution

In this section, we consider the completely unknown distribution setting. Under this setting, we first divide the incoming \( T \) requests into multiple stages and run an inner loop similar to Algorithm 2 with the estimate of the optimal objective value in each stage. More specifically, the differences between the inner loop and Algorithm 2 are three-fold: i). choose the deviation parameter \( \delta = \epsilon \) instead of \( \tau \), where \( \epsilon \) is an error parameter defined in Theorem 4.5; ii). pessimistically reduce the estimated objective value from \( W_{r-1} \) to \( Z_r \) in each stage for boosting the chance of success, where \( W_{r-1} \) is estimated by Algorithm 3; iii). consider the relative error of objective and the maximum relative error of constraints as \( \epsilon_y, \gamma \) and \( \epsilon_x, \gamma \) separately in each stage, instead of using the global error parameter \( \epsilon \). We consider that \( \epsilon_y, \gamma \) describes the error we care about the most (objective) and \( \epsilon_x, \gamma \) describes the rest errors (constraints and objective estimates). Distinguishing these error terms allows for more refined results, but will lead to the competitive ratio of the same order in our settings. In Algorithm 4, we name the proposed algorithm by \( A_1 \) to facilitate the analysis.

The high-level ideas can be summarized as follows. There are three types of errors that have to be restrained, 1). the error \( |Z_r - W_r| \) from estimating deviant objective value, 2). the error \( \epsilon_x, \gamma \) from guaranteeing the satisfaction of constraints, and 3). the error \( \epsilon_y, \gamma \) from Algorithm 1 affected by the randomness in the objective. We use an iterative learn-and-predict strategy to periodically reduce relative errors caused by insufficient samples. Let \( \tilde{W}_r \) be the objective obtained by Algorithm 1 in stage \( r \). According to the previous sections, if objective \( Z_r \) is reachable, we could prove that the loss \( \ell_r := |\tilde{W}_r - Z_r| \) is upper bounded by \( O(\frac{1}{T} \epsilon_y, \gamma Z_r) \) in each stage. We also need \( Z_r \) to be a good estimate for the objective. \( Z_r \geq (1 - O(\epsilon_x, r-1))W_r \).
Algorithm 3 Objective Estimator \( \{ \text{request}_r, t_r, \beta \} \)

1. **Input:** requests from \( r \)-th stage \( \{ \text{request}_r \} \), request number \( t_r \), deviation parameter \( \beta \).
2. **Output:** \( W^r \)
3. Solve \( E(\beta) \) as

\[
W^r = \max_x \sum_{i\in\mathcal{I}} \sum_{j=1}^{t_r} w_{ij} x_{ij} \\
\text{s.t. } \frac{t_r}{T} (L_k + \beta T \bar{a}_k) \leq \sum_{i\in\mathcal{I}} \sum_{j=1}^{t_r} a_{ij} x_{ij} \\
\leq \frac{t_r}{T} U_k, \forall k \in \mathcal{K} \\
\sum_{i\in\mathcal{I}} x_{ij} \leq 1, \forall j \in [t_r] \\
x_{ij} \geq 0, \forall i \in \mathcal{I}, j \in [t_r]
\]

\( W^r \) ensures that the objective is not underestimated, and \( Z_r \leq W_e \) ensures that it is a reachable target and facilitates the proof for \( r = 0, \ldots, l - 1 \). Besides the normal stages, a warm-up stage \( r = -1 \) is added to provide an estimate \( Z_1 \). Then the cumulative loss \( \ell_{-1} + \sum_{r=0}^{l-1} \ell_r \) will be no greater than \( O\left( \frac{T}{T} W_0 + \sum_r \frac{t_r (1+\epsilon_r)}{\epsilon_r} W_e \right) \). The algorithm is designed to balance the relative error \( \epsilon_{x,r}, \epsilon_{y,r} \) and their impact on the requests in each stage.

More precisely, Algorithm \( A_1 \) geometrically divides \( T \) requests into \( l + 1 \) stages, where the number of requests are \( t_r = \epsilon 2^T \) for \( r = 0, \ldots, l - 1 \) and \( t_{-1} = \epsilon T \). In the initial stage \( r = -1 \), we use the first \( t_r = \epsilon T \) requests to estimate \( W_2 \) and obtain \( W^{-1} \), assuming that none of the requests are served in worst case. In stage \( r \in \{0, 1, \ldots, l - 1\} \), the requests from stage \( r - 1 \) are used to provide more and more accurate estimate \( W^{r-1} \) of \( W_e \). By Union Bound, we set the failure probability as \( \delta = \frac{\epsilon}{2^T} \) and reduce the estimate \( W^{r-1} \) to \( Z^r = \frac{T}{t_r (1+O(\epsilon_{x,r}-1))} \), which is promised between \( \left[ (1 - O(\epsilon_{x,r}-1)) W_e, W_e \right] \) w.p. \( 1 - 2\delta \).

Then in each stage \( r \), define the error parameters for objective and constraints as \( \epsilon_{y,r} = O\left( \sqrt{\frac{\ln(K/\delta)}{t_r \epsilon_r}} \right) \) and \( \epsilon_{x,r} = O\left( \sqrt{\frac{\sqrt{\ln(K/\delta)}}{t_r \epsilon_r}} \right) \) respectively. We construct a surrogate Algorithm \( \tilde{P}_2 \) that achieves \( T (1-\epsilon_{y,r}) Z^r \) cumulative revenue with the consumption of every resource \( k \) between \( \left[ \frac{t_r (1+\epsilon_r)}{T} (L_k + (\epsilon - \epsilon_{x,r}) T \bar{a}_k), \frac{t_r (1+\epsilon_r)}{T} U_k \right] \) with probability at least \( 1 - \delta \). Similar to previous sections, the connection between the inner loop of Algorithm \( A_1 \) and Algorithm \( \tilde{P}_2 \) is built to minimize the upper bound of failure probabilities. Finally, with probability at least \( 1 - \delta \), the cumulative revenue is at least \( \sum_{r=0}^{l-1} \frac{t_r Z_r}{T} (1 - \epsilon_{y,r}) \) and the cumulative consumed resource of \( k \in \mathcal{K} \) is between \( \sum_{r=0}^{l-1} \frac{t_r (1+\epsilon_r)}{T} (L_k + (\epsilon - \epsilon_{x,r}) T \bar{a}_k) \) and \( \sum_{r=0}^{l-1} \frac{t_r (1+\epsilon_r)}{T} U_k \). Letting \( \gamma_1 = O\left( \frac{\epsilon^2}{(1+\epsilon_r)^2} \right) \), we could keep \( \sum_{r=0}^{l-1} \frac{t_r}{T} (1+\epsilon_r) U_k \leq U_k \) and \( \sum_{r=0}^{l-1} \frac{t_r (1+\epsilon_r)}{T} (L_k + (\epsilon - \epsilon_{x,r}) T \bar{a}_k) \geq L_k \) and \( \sum_{r=0}^{l-1} \frac{t_r Z_r}{T} (1 - \epsilon_{y,r}) \geq (1 - O(\frac{\epsilon^2}{\epsilon_{x,r}})) W_0 \).

The most tricky part of Algorithm \( A_1 \) is estimating \( W^r \) in Algorithm \( 3 \). Since the lower bound \( L_k \) cannot upper bound the mean of \( X_{jk} \) as \( U_k \) does, it brings a great challenge to the theoretical analysis. To address this issue, we solve a biased LP problem, upfiling \( L_k \) by \( c T \bar{a}_k \), at the end of each stage. It helps the satisfaction of the lower bound in the next stage, and the influence on the objective can be determined by Theorem 4.2. This completes the high-level overview of the analysis of Algorithm \( A_1 \). The theoretical result of Algorithm \( A_1 \) is presented in Theorem 4.5 with explicit requirements of parameters.

**Theorem 4.5.** Under Assumption 7.3 if \( \epsilon > 0 \) and \( \tau_1 = \frac{\epsilon^2}{1-\sqrt{\epsilon}} \) such that \( \tau_1 + \epsilon \leq \xi^* \) and \( \gamma_2 = \max \left( \frac{\epsilon^2}{\ln(K}), \frac{\epsilon^2}{\ln(1/\delta)} \right) \), Algorithm \( A_1 \) defined in Algorithm 4 achieves an objective value of at least \( (1 - O(\frac{\epsilon^2}{\epsilon_{x,r}})) W_0 \) and satisfies the constraints w.p. \( 1 - \epsilon \).

The proof of the theorem is deferred to Appendix G.

**Remark:**

1. It can be shown that the problem dependent parameter \( \xi^* \) restricts the capacity of Algorithm \( A_1 \) by affecting \( \epsilon, \tau_1, \) and \( \gamma_1 \). This is consistent with our intuition that the problem with two-sided constraints becomes harder if \( \xi^* \) decreases.
2. It is worth noting that the competitive ratio obtained in this paper reflects the high-probability performance of the proposed algorithms under a finite \( T \), so it is difficult to compare with the regret bound for dual-mirror-descent methods rigorously due to the different settings. But if \( T \) is given and the linear growth of lower and upper bound is assumed, i.e. \( L_k \) and \( U_k \) are both \( O(T) \), \( \xi^* \) turns to be a problem-dependent constant, which leads the proposed algorithm towards an \( O\left( \sqrt{T \ln(K T)} \right) \) regret w.h.p., where we hide the potential log-term in \( O() \). In real-world applications with massive constraints, such as guaranteed advertising delivery \( [Zhang et al., 2020] \) with hundreds of thousands of ad providers, the proposed algorithm could exceed existing \( O\left( \sqrt{T K} \right) \) averaged regrets \( [Balseiro et al., 2020; 2021; Lobos et al., 2021] \) with respect to the number of constraints \( K \). More comparisons can also be found in \( [Devanur et al., 2019] \).

18: end for

stage, according to the proof of Theorem G.2, we can use the revenue obtained from previous stage as a good approximation of $W^{r-1}$ before Algorithm 3, returning it in practice for $r = 1, \ldots, l - 1$. Thus, the online property of Algorithm 4 will not be hurt severely.

However, sometimes $\xi^*$ is inapplicable in practice when Algorithm 3 is initialized. We will address the unknown measurement $\xi^*$ in the next section.

5. Exploring the Measure of Feasibility

As shown in previous sections, the constant $\xi^*$ measures the feasibility of the original problem, and plays a central role in Algorithm A1. $\xi^*$ can hardly be obtained in practice. Motivated by Algorithm 3, we propose Algorithm 5 for estimating $\xi$ to provide a more complete analysis. In this section, we investigate the strong feasible condition, i.e., Assumption 3. Recalling the definition of $E(\beta)$ in Section 3, we can conclude the following results.

Algorithm 5 Feas_Estimator($\{\text{request}_j\}_{r-1, t_{r-1}}, t_r, \gamma_2, \delta$)

1: Input: requests from $r$-th stage $\{\text{request}_j\}_{r-1, t_{r-1}}, t_r, \gamma_2, \delta$
2: Output: $\hat{\xi} = \max(\frac{\hat{a}_k}{t_r}, \frac{\hat{a}_k}{T a_k - L_k}) = O(\frac{\epsilon^2}{\ln(K)})$
3: Compute $\epsilon_{x,r} = \sqrt{\frac{4 T \ln(K/\delta)}{t_r}}$
4: Set $\hat{\xi}_{max} = \max(\hat{\xi}, \epsilon_{x,r})$
5: \text{s.t.} $t_r^{\gamma_2} (L_k + \epsilon T a_k) \leq \sum_{i \in K} \sum_{j=t_{r+1}} t_{r+1} a_{ij,k} x_{ij} \leq t_r U_k, \forall k \in K$
6: $x_{ij} \geq 1, \forall i \in I, j = t_r + 1, \ldots, t_{r+1}$

Algorithm 6 Algorithm A2

1: Input: $\epsilon, L_k, U_k, \gamma_1, \gamma_2 = O(\frac{\epsilon^2}{\ln(K)})$
2: Output: $\{x_{ij}\}_{i \in I, j \in [T]}$
3: Set $l = \log_2(\frac{1}{\epsilon})$, $t_r = \epsilon 2^r T$, $t_{r-1} = \epsilon T$ and $\delta = \frac{\epsilon}{3^r}$
4: Set $\hat{\xi}_0 = \text{Feas_Estimator}(\{\text{request}_j\}_{r-1, t_{r-1}}, t_r, \gamma_2, \delta)$
5: Execute the Algorithm A1($\epsilon, \gamma_1, \xi_0$)

Proposition 5.1. According to the definition of $\xi^*$ in LP [4], we have
1. When $\xi^* \geq 0$, the problem $E(0)$ is feasible. Otherwise, it is infeasible.
2. When $\xi^* > 0$ and $0 < \xi \leq \xi^*$, the problem $E(\xi)$ is feasible.

We omit the proof of the proposition for simplicity. From Proposition 5.1, with the knowledge of $\xi^*$, we could easily check the feasibility of $E(0)$. Next, we show how to estimate the $\xi^*$ from served requests in Algorithm 5.

Theorem 5.2. Under Assumption 7, if $\gamma_2 = \max(\frac{\hat{a}_k}{t_r}, \frac{\hat{a}_k}{T a_k - L_k}), O(\frac{\epsilon^2}{\ln(K)})$, Algorithm 5 with $t_r$ i.i.d. requests outputs $\hat{\xi}$ such that $\hat{\xi} \in [\xi^* - 4 \epsilon_{x,r}, \xi^*]$ w.p. $1 - 2\delta$, where $\epsilon_{x,r} = \sqrt{\frac{4 T \ln(K/\delta)}{t_r}}$.

The proof is deferred to Appendix H.

Now $\hat{\xi}$ can be viewed as a good estimate for $\xi^*$ from stage 0. Based on the estimation of $\xi^*$, we propose an algorithm A2 in Algorithm 6. Like the previous methods, we geometrically divide $T$ requests into $l + 1$ stages for $r = -1, 0, \ldots, l - 1$, where the initial stage $r = -1$ and the first stage $r = 0$ have $\epsilon T$ requests. Besides the estimate $W^{r-1}$, the estimate $\hat{\xi}_0$ for $\xi^*$ is obtained by Algorithm 5 at the end of the initial stage $r = -1$. Then we consider the
new expected problem $E\left(\hat{w}_0\right)$ and run Algorithm $A_1$ defined in Algorithm 4 for the rest requests.

**Theorem 5.3.** Under Assumption 1-3, if $\varepsilon > 0$, $\tau_1 = \frac{\sqrt{\varphi}}{1 - \sqrt{\varphi}}$ such that $\gamma_1 + 4\sqrt{\varphi} + \varepsilon \leq \xi^*$ and $\gamma_1 = \max\left(\frac{\xi}{\varphi}, \frac{\eta}{(1 - \varphi)\varphi_0 - \xi} - \xi\right) W_{0} \leq O\left(\frac{\varepsilon^2}{\ln(\frac{1}{\varepsilon})}\right)$, Algorithm 6 achieves an objective value of at least \(1 - O\left(\frac{\varepsilon^2}{\ln(\frac{1}{\varepsilon})}\right)W_{0}\) and satisfies the constraints, w.p. $1 - \varepsilon$.

The proof can be found in Appendix C.

Until now, we have dropped the knowledge of the entire distribution $P$, the objective value $W_{\tau}$ for problem $E(\tau)$ and the strong feasible constant $\xi^*$ step by step. In practice, the only hyperparameter $\epsilon$ can be well approximated by solving a polynomial approximation of the transcendental equation between $\gamma_1$ and $\epsilon$ in Theorem 5.3. We regard the proposed Algorithm 6 as a practical algorithm for two-sided constrained online resource allocation problems.

### 6. Conclusion

In this paper, we have developed a method for online allocation problems with two-sided resource constraints, which has a wide range of real-world applications. By designing a factor-revealing linear fractional programming, a measure of feasibility $\xi^*$ is defined to facilitate our theoretical analysis. We prove that Algorithm 6 holds a nearly optimal competitive ratio if the measurement is known and large enough compared with the error parameter, i.e. $\xi^* \gg \varepsilon$. An estimator is also presented in the paper for the unknown $\xi^*$ scenario. We will investigate more efficient extensions of this work in the near future.

Nearly Optimal Competitive Ratio for Online Allocation Problems with Two-sided Resource Constraints and Finite Requests

A. The Examples of Resource Lower Bounds

In this section, we give three practical instances showing the necessity of lower bound constraints in real-world applications.

1. **Guaranteed Advertising Delivery**: In the online advertising scenario, the advertising publishers will sell the ad impressions in advance with the promise to provide each advertiser an agree-on number of target impressions over a fixed future time period, which is usually written in the contracts. Furthermore, the advertising platform considers other constraints, such as advertisers’ budgets and impressions inventories, and simultaneously maximizes multiple accumulative objectives regarding different interested parties, e.g., Gross Merchandise Volume (GMV) for ad providers and publisher’s revenue. This widely used guaranteed delivery advertising model is generally formulated as an online resource allocation problem with two-sided constraints (Zhang et al., 2020).

2.1. **Fair Channel Constraints**: We consider the online orders assignment in an e-commerce platform, where the platform allocates the orders (or called packages in logistics) to different warehouses providers. Due to the governmental regulations and contracts between platforms and providers, the platform usually tends to set lower bounds to the daily accepted orders for special channels, such as new/small-scale providers or those in developing areas. Besides, it can be shown that when providers are concerned about fairness, the platform can use a simple wholesale price above its marginal cost to coordinate this channel in terms of both achieving the maximum channel profit and attaining the maximum channel utility (Haitao Cui et al., 2007).

2.2. **Timeliness Achievement Constraints**: The delivery time for orders is highly related with the customers’ shopping experience. Thus, the online shopping platforms also take the time-effectiveness of parcel shipment into account. For every parcel, platforms usually use the timeline achievement rate $r_{uov}$ to denote the probability of arriving at the destination in required $u$ days if we assign the order of type $o$ to one channel $v$, which could be estimated by the historical data and features of order and channel/logistics providers. As we know, long delivery time will impair the consumer’s shopping experience, but reducing delivery time means increasing cost. In order to balance the customers’ shopping experience and transportation costs, platforms always set a predefined lower threshold to the average timeline achievement rate of daily orders, which can be modeled as lower bound constraints in order assignment task.

B. Useful Concentrations

In this section, we present the classical concentration inequalities for completeness.

**Lemma B.1.** (Bernstein, 1946)

1. Suppose that $|X| \leq c$ and $\mathbb{E}[X] = 0$. For any $t > 0$,

   \[ \mathbb{E}[\exp(tX)] \leq \exp \left( \frac{\sigma^2}{2c^2} (e^{tc} - 1 - ct) \right) \]

where $\sigma^2 = \text{Var}(X)$.

2. If $X_1, X_2, \ldots, X_n$ are independent r.v., $\mathbb{E}[X_i] = \mu$ and $\mathbb{P}(|X_i - \mu| \leq \varepsilon) = 1, \forall i = 1, \ldots, n$, then $\forall \varepsilon > 0$ following inequality holds

   \[ \mathbb{P}\left( \left| \frac{\sum_{i=1}^{n} X_i}{n} - \mu \right| \geq \varepsilon \right) \leq 2 \exp \left( - \frac{n\varepsilon^2}{2\sigma^2 + \frac{2\sigma \varepsilon}{3}} \right) \]

where $\sigma^2 = \frac{\sum_{i=1}^{n} \text{Var}(X_i)}{n}$.

The first result, Lemma B.1i., is a well-known intermediate result of Bennett’s inequality. We go a few steps further to construct the algorithm.

C. Proof for Lemma 3.1

**Lemma 3.1.** $W_0 \geq \mathbb{E}[W_R]$. 

Proof. We consider two linear programming problem, the linear relaxation of sampled integer linear programming (1), i.e.
\[
\max_x \sum_{i \in I, j \in [T]} w_{ij} x_{ij} \\
\text{s.t. } L_k \leq \sum_{i \in I, j \in [T]} \alpha_{ijk} x_{ij}, \forall k \in \mathcal{K} \\
\sum_{i \in I} x_{ij} \leq 1, \forall j \in [T] \\
x_{ij} \geq 0, \forall i \in I, j \in [T]
\]
and the linear programming that considers the samples from the type of requests perspective, i.e.
\[
\max_x \sum_{i \in I, j \in J} |\{j' | j' \in [T], j' = j\}| w_{ij} x_{ij} \\
\text{s.t. } \sum_{i \in I} x_{ij} \leq 1, \forall j \in J \\
x_{ij} \geq 0, \forall i \in I, j \in J
\]
where $|\cdot|$ denote the cardinality of a given set. We use the $W_{R_1}$ and $W_{R_2}$ to denote the optimal value of Sample Instance (S.I I) and (S.I II) respectively. Because the LP (S.I I) is a relaxation version of ILP (1), we know that $W_{R_1} \geq W_{R_2}$. For any optimal solution $\{x_{ij}^* | \forall i \in I, j \in [T]\}$ of LP (S.I I), it’s easy to verify that the solution $\{x_{ij}^* | \forall i \in I, j \in J\}$ is feasible for LP (S.I II), so that $W_{R_2} \geq W_{R_1}$. Moreover, the average of optimal solution for all possible LP (S.I II) is a feasible solution for LP (2), $\beta = 0$, whose optimal solution is $W_0$. Thus $W_0 \geq E[W_{R_2}] \geq E[W_{R_1}] \geq E[W_R]$.

D. Proof of Theorem 4.2

Theorem 4.2. Under the strong feasible condition in Assumption 3, the optimal objective of $E(\tau)$ satisfies that
\[
W_{\tau} \geq \left( 1 - \frac{\tau}{\xi^*} \right) W_0,
\]
where $\tau = \frac{\xi}{1-\xi}$.

Proof. The dual problem of the expected instance, i.e., problem $E(0)$, is
\[
\min_{\alpha, \beta, \rho} \sum_{k \in \mathcal{K}} \alpha_k U_k - \sum_{k \in \mathcal{K}} \beta_k L_k + \sum_{j \in J} \rho_j \\
\text{s.t. } \sum_{k \in \mathcal{K}} (\alpha_k - \beta_k) Tp_j a_{ijk} - Tp_j w_{ij} + \rho_j \geq 0, \\
\forall i \in I, j \in J, \\
\alpha_k, \beta_k, \rho_j \geq 0, k \in \mathcal{K}, j \in J,
\]
and the dual problem of $E(\tau)$ is
\[
\min_{\alpha, \beta, \rho} \sum_{k \in \mathcal{K}} \alpha_k U_k - \sum_{k \in \mathcal{K}} \beta_k (L_k + \tau T \bar{a}_k) + \sum_{j \in J} \rho_j \\
\text{s.t. } \sum_{k \in \mathcal{K}} (\alpha_k - \beta_k) Tp_j a_{ijk} - Tp_j w_{ij} + \rho_j \geq 0, \\
\forall i \in I, j \in J, \\
\alpha_k, \beta_k, \rho_j \geq 0, k \in \mathcal{K}, j \in J.
\]
It can be observed that LP (8) and LP (9) share the same feasible set, while LP (9) has an extra term $- \sum_{k \in \mathcal{K}} \tau T \bar{a}_k \beta_k$ in the
We investigate the dual problem of LP (11) as follows.

By the first constraint of LP (12), it can be observed that

\[ \alpha_k, \beta_k, \rho_j \geq 0, k \in K, j \in J. \]

Since \( \sum_{k \in K} \alpha_k U_k - \sum_{k \in K} \beta_k L_k + \sum_{j \in J} \rho_j \geq W_0 > 0 \) for any dual feasible solution, we can do the following transformation

\[
\begin{align*}
\bar{\alpha}_k &= \frac{\alpha_k}{\sum_{k \in K} \alpha_k U_k - \sum_{k \in K} \beta_k L_k + \sum_{j \in J} \rho_j} \\
\bar{\beta}_k &= \frac{\beta_k}{\sum_{k \in K} \alpha_k U_k - \sum_{k \in K} \beta_k L_k + \sum_{j \in J} \rho_j} \\
\bar{\rho}_j &= \frac{\rho_j}{\sum_{k \in K} \alpha_k U_k - \sum_{k \in K} \beta_k L_k + \sum_{j \in J} \rho_j} \\
z &= \frac{1}{\sum_{k \in K} \alpha_k U_k - \sum_{k \in K} \beta_k L_k + \sum_{j \in J} \rho_j}.
\end{align*}
\]

In this way, we transfer the linear fractional programming (10) into

\[
\begin{align*}
\max_{\bar{\alpha}, \bar{\beta}, \bar{\rho}} \sum_{k \in K} \frac{\epsilon}{1 - \epsilon} \bar{T}_{\bar{\alpha}_k \bar{\beta}_k} \\
s.t. \quad \sum_{k \in K} (\bar{\alpha}_k - \bar{\beta}_k) T p_j a_{ijk} - T p_j w_{ij} \bar{\rho}_j \geq 0, \\
\forall i \in I, j \in J \\
\sum_{k \in K} \bar{\alpha}_k U_k - \sum_{k \in K} \bar{\beta}_k L_k + \sum_{j \in J} \bar{\rho}_j = 1 \\
\bar{\alpha}_k, \bar{\beta}_k, \bar{\rho}_j, z \geq 0, k \in K, j \in J.
\end{align*}
\]

We investigate the dual problem of LP (11) as follows.

\[
\begin{align*}
\min_t \quad & t \leq t \\
s.t. \quad & \sum_{i \in I} d_{ij} \leq t \\
& \sum_{i \in I, j \in J} d_{ij} T p_j a_{ijk} \leq t U_k \\
& \sum_{i \in I, j \in J} d_{ij} T p_j a_{ijk} \geq t L_k + \frac{\epsilon}{1 - \epsilon} T \bar{\alpha}_k \\
& \forall d_{ij} \geq 0, t \in \mathbb{R}, \forall i \in I, j \in J.
\end{align*}
\]

By the first constraint of LP (12), it can be observed that \( t \geq 0 \) holds. With the auxiliary variable \( z_{ij} \) which makes
$d_{ij} = tz_{ij}$, we reformulate LP (12) into

$$t^* = \min_{t, z} \left( \sum_{i \in I} z_{ij} - 1 \right) \leq 0$$

subject to

$$t \left( \sum_{i \in I, j \in J} z_{ij} Tp_i a_{ijk} - U_k \right) \leq 0$$

$$t \left( \sum_{i \in I, j \in J} z_{ij} Tp_i a_{ijk} - L_k \right) \geq \frac{\varepsilon}{1 - \varepsilon} T \bar{a}_k$$

for all $z_{ij} \geq 0, t \geq 0, \forall i \in I, j \in J$.

According to the strong feasible condition Assumption 3, there exists a feasible solution $\{x'_{ij} \mid x'_{ij} \geq 0\}$ to LP (3) such that $\sum_{i \in I, j \in J} x'_{ij} T p_i a_{ijk} \leq U_k$, $\sum_{i \in I, j \in J} T p_i a_{ijk} x'_{ij} \geq L_k + \xi^* T \bar{a}_k$ and $\sum_{i \in I} x'_{ij} \leq 1, \forall k \in K$. Therefore, $t = \frac{\xi^*}{\xi}$ and $z_{ij} = x'_{ij}$ $\forall i \in I, j \in J$ is a feasible solution to LP (13). As a result, we have $t^* \leq \frac{\xi^*}{\xi}$. Since LP (10) has the same optimum as LP (13), we have that

$$\sum_{k \in K} \alpha_k U_k - \sum_{k \in K} \beta_k L_k + \sum_{j \in J} \rho_j \geq \left(1 - \frac{T}{\xi^*}\right) \left(\sum_{k \in K} \alpha_k U_k - \sum_{k \in K} \beta_k L_k + \sum_{j \in J} \rho_j\right)$$

under the constraint of LP (8). Therefore, $W_{\tau} \geq \left(1 - \frac{T}{\xi^*}\right)W_0$.

The factor-revealing linear fractional programming analysis shows the way we develop the definition of $\xi^*$ and enlightens the design of feasibility estimator in Algorithm 5. Besides, the proof framework is reused in proving Lemma G.1.

E. Proof of Lemma 4.1 and Theorem 4.3

We restate the Lemma 4.1 as follows.

**Lemma 4.1.** Under Assumption 4.3, if $\forall \varepsilon > 0$ and $\gamma = \max \left( \frac{a_k}{U_k}, \frac{\bar{a}_k}{\bar{T} a_k - L_k}, \frac{\bar{a}_k}{W_{\tau}} \right) = O\left(\frac{\varepsilon^2}{\ln(K/\varepsilon)}\right)$, Algorithm 4 achieves an objective value at least $(1 - 2\varepsilon)W_{\tau}$ and satisfies the constraints w.p. $1 - \varepsilon$.

**Proof.** We first prove that, for every resource $k$, the consumed resource is below the capacity $U_k$ w.h.p.,

$$P \left( \sum_{j=1}^{T} X_{jk}^\tilde{p} \geq U_k \right)$$

$$= P \left( \sum_{j=1}^{T} (X_{jk}^\tilde{p} - \mathbb{E}[X_{jk}^\tilde{p}]) \geq U_k - \mathbb{E}[X_{jk}^\tilde{p}] \right)$$

$$\leq \exp \left\{ - \frac{\left( U_k - \mathbb{E}[X_{jk}^\tilde{p}] \right)^2}{2T \sigma^2 + \frac{2}{3} a_k \left( U_k - \mathbb{E}[X_{jk}^\tilde{p}] \right)} \right\}$$

$$= \exp \left\{ - \frac{U_k - \mathbb{E}[X_{jk}^\tilde{p}]}{2T \sigma^2 + \frac{2}{3} a_k \left( U_k - \mathbb{E}[X_{jk}^\tilde{p}] \right)} \right\}$$

(14)
where the first inequality follows from $E[X_{jk}^{\tilde{P}}] = E[X_{2j}^{\tilde{P}}] = \cdots = E[X_{Tj}^{\tilde{P}}]$; the first inequality from Lemma B.1 and setting $\sigma^2 = Var(X_{jk}^{\tilde{P}})$; in the second inequality, it could verify that $\sigma^2 \le E[(X_{jk}^{\tilde{P}})^2] \le \bar{a}_k E[X_{jk}^{\tilde{P}}] \le \frac{(1-\bar{a}_k) T \bar{a}_k - T_{\bar{a}_k - L_k}}{T \bar{a}_k - T_{X_{jk}^{\tilde{P}}} - L_k}$, $TE[X_{jk}^{\tilde{P}}] - L_k \ge \varepsilon (T \bar{a}_k - L_k)$, and $\sigma^2 \le \bar{a}_k \frac{1-\varepsilon}{\varepsilon}$ so that $-\frac{\varepsilon U_k}{2 \sigma^2} \le -\frac{\varepsilon U_k}{2 \sigma^2} \frac{\bar{a}_k}{T \bar{a}_k - T_{X_{jk}^{\tilde{P}}} - L_k} = -\frac{\varepsilon^2}{2(1-\varepsilon) \sigma^2}$; the final inequality from $\gamma \ge \frac{\alpha_k}{U_k}$; the final inequality from $\gamma = O\left(\frac{\varepsilon^2}{\ln(\frac{1}{\varepsilon})}\right)$.

Next, we verify that the Algorithm $\tilde{P}$ satisfies the lower resource bound with high probability.

$$P\left(\sum_{j=1}^{T} X_{jk}^{\tilde{P}} \le L_k\right)$$

$$= P\left(\sum_{j=1}^{T} \left( E[X_{jk}^{\tilde{P}}] - X_{jk}^{\tilde{P}} \right) \ge TE[X_{jk}^{\tilde{P}}] - L_k\right)$$

$$\le \exp\left\{ -\frac{\varepsilon^2}{2(1-\frac{2}{\varepsilon}) \frac{\bar{a}_k}{T \bar{a}_k - T_{X_{jk}^{\tilde{P}}} - L_k}}\right\}$$

$$= \exp\left\{ -\frac{\varepsilon^2}{2 \sigma^2} \frac{\bar{a}_k}{T \bar{a}_k - T_{X_{jk}^{\tilde{P}}} - L_k}\right\}$$

$$\le \frac{\varepsilon}{2K + 1}$$

where the first inequality from Lemma B.1 and setting $\sigma^2 = Var(X_{jk}^{\tilde{P}})$; in the second inequality, we could verify that $\sigma^2 = Var(X_{jk}^{\tilde{P}}) = Var(\bar{a}_k - X_{jk}^{\tilde{P}}) \le E[(\bar{a}_k - X_{jk}^{\tilde{P}})^2] \le \bar{a}_k E[\bar{a}_k - X_{jk}^{\tilde{P}}] \le \frac{(1-\bar{a}_k) T \bar{a}_k - T_{\bar{a}_k - L_k}}{T \bar{a}_k - T_{X_{jk}^{\tilde{P}}} - L_k}$, $TE[X_{jk}^{\tilde{P}}] - L_k \ge \varepsilon (T \bar{a}_k - L_k)$, and $\sigma^2 \le \bar{a}_k \frac{1-\varepsilon}{\varepsilon}$ so that $-\frac{\varepsilon U_k}{2 \sigma^2} \le -\frac{\varepsilon U_k}{2 \sigma^2} \frac{\bar{a}_k}{T \bar{a}_k - T_{X_{jk}^{\tilde{P}}} - L_k} = -\frac{\varepsilon^2}{2(1-\varepsilon) \sigma^2}$; the final inequality from $\gamma \ge \frac{\alpha_k}{U_k}$; the final inequality from $\gamma = O\left(\frac{\varepsilon^2}{\ln(\frac{1}{\varepsilon})}\right)$.

Therefore, from the previous outcomes, the consumed resource $k$ satisfies our lower and upper bound requirements, w.h.p. Next, we investigate the revenue the Algorithm $\tilde{P}$ brings.

$$P\left( \sum_{j=1}^{T} Y_{jk}^{\tilde{P}} \le (1 - 2\varepsilon) W_T \right)$$

$$= P\left( \sum_{j=1}^{T} \left( E[Y_{jk}^{\tilde{P}}] - Y_{jk}^{\tilde{P}} \right) \ge TE[Y_{jk}^{\tilde{P}}] - (1 - 2\varepsilon) W_T \right)$$

$$\le \exp\left\{ -\frac{\left( TE[Y_{jk}^{\tilde{P}}] - (1 - 2\varepsilon) W_T \right)^2}{2 \sigma^2 + \frac{2}{\varepsilon} \bar{w} \left( TE[Y_{jk}^{\tilde{P}}] - (1 - 2\varepsilon) W_T \right)}\right\}$$

15
Nearly Optimal Competitive Ratio for Online Allocation Problems with Two-sided Resource Constraints and Finite Requests

\[
= \exp \left\{ -T\mathbb{E}[Y^\hat{P}] - (1 - 2\varepsilon)W_\tau \right\} \\
\leq \exp \left\{ -\frac{\varepsilon^2}{2(1 - \frac{3}{4}\varepsilon) \hat{w}} \right\} \\
\leq \frac{\varepsilon}{2K + 1}
\]

where the first equality follows from \( \mathbb{E}[Y_1^\hat{P}] = \mathbb{E}[Y_2^\hat{P}] = \cdots = \mathbb{E}[Y_T^\hat{P}] \); the first inequality from Lemma B.1 and setting \( \sigma_1^2 = \text{Var}(Y_j^\hat{P}); \) in the second inequality, we could easily verify that \( \sigma_1^2 \leq \mathbb{E}[(Y_j^\hat{P})^2] \leq \hat{w}\mathbb{E}[Y_j^\hat{P}] \leq \frac{(1 - \varepsilon)\hat{w}W_\tau}{2} \) and \( \mathbb{E}[Y_j^\hat{P}] = (1 - \varepsilon)\frac{W_\tau}{\hat{w}} \) so that \( \frac{T\mathbb{E}[Y_j^\hat{P}] - (1 - 2\varepsilon)W_\tau}{T\sigma_1^2} \leq \frac{\varepsilon W_\tau}{2\hat{w} \frac{3}{4}\varepsilon + \frac{3}{4}\hat{w}} = -\frac{\varepsilon^2}{2(1 - \frac{3}{4}\varepsilon) \frac{3}{4}\hat{w}} \); the final inequality follows from \( \gamma = O(\frac{\varepsilon^2}{\ln(\frac{3}{4})}) \).

From equation (14) - (16),
\[
P(\sum_{j=1}^{T} Y_j^\hat{P} \leq (1 - 2\varepsilon)W_\tau) + \sum_{k \in K} P(\sum_{j=1}^{T} X_{jk}^\hat{P} \notin [L_k, U_k]) \\
\leq (2K + 1) \frac{\varepsilon}{2K + 1} \leq \varepsilon
\]
when \( \gamma = O(\frac{\varepsilon^2}{\ln(\frac{3}{4})}) \), where \( \gamma = \max(\frac{\bar{w}}{W_\tau}, \frac{\bar{a}_k}{T\bar{a}_k - L_k}, \frac{\bar{a}_k}{T\bar{a}_k + U_k}) \).

\[\textbf{Theorem 4.3.} \quad \text{Under Assumption 4.3 if } 0 < \varepsilon < \frac{1}{\tau}, \text{ then } \gamma = O(\frac{\varepsilon^2}{\ln(\frac{3}{4})}), \text{ Algorithm 4 achieves an objective value of at least } (1 - (2 + \frac{1}{\tau})\varepsilon)W_0 \text{ and satisfies the constraints w.p. } 1 - \varepsilon.\]

With Assumption 4.3 Theorem 4.2 and Lemma 4.1 the cumulative revenue is larger than \( (1 - 2\varepsilon)W_\tau \geq (1 - 2\varepsilon)(1 - \frac{\tau}{\varepsilon})W_0 \geq (1 - (2 + \frac{1}{\tau})\varepsilon)W_0 \). We finish the proof of Theorem 4.3

\[\textbf{F. Proof of Theorem 4.4} \]

\[\textbf{Theorem 4.4.} \quad \text{Under Assumption 4.3 if } 0 < \varepsilon < \frac{1}{\tau}, \text{ then the Algorithm 2 achieves an objective value at least } (1 - (2 + \frac{1}{\tau})\varepsilon)W_0 \text{ and satisfies the constraints w.p. } 1 - \varepsilon.\]

\[\textbf{Proof.}\] We consider the good event defined by
\[
G := \left\{ \sum_{j=1}^{s} X_{jk}^A + \sum_{j=s+1}^{T} X_j^\hat{P} \leq U_k, \forall k \in K \right\} \cap \left\{ \sum_{j=1}^{s} X_{jk}^A + \sum_{j=s+1}^{T} X_j^\hat{P} \geq L_k, \forall k \in K \right\} \\
\cap \left\{ \sum_{j=1}^{s} Y_{jk}^A + \sum_{j=s+1}^{T} Y_j^\hat{P} \geq (1 - 2\varepsilon)W_\tau \right\}
\]
\[= G_1 \cap G_2 \cap G_3,\]
which means the hybrid Algorithm \( A^*\hat{P}^{T-s} \) can achieve at least \( (1 - 2\varepsilon)W_\tau \) revenue while satisfying the two-side constraints. We will show that the probability of the complement event \( G^c \) can be bounded by some moment generating functions.
Nearly Optimal Competitive Ratio for Online Allocation Problems with Two-sided Resource Constraints and Finite Requests

For the first bad event $G^s_1$, we have

$$P\left(\sum_{j=1}^{s} X_{jk}^A + \sum_{j=s+1}^{T} X_{jk}^\tilde{P} \geq U_k\right)$$

$$\leq \min_{t>0} \mathbb{E}\left[ \exp(t\left(\sum_{j=1}^{s} X_{jk}^A + \sum_{j=s+1}^{T} X_{jk}^\tilde{P} - U_k\right))\right]$$

$$= \min_{t>0} \mathbb{E}\left[ \exp(t\left(\sum_{j=1}^{s} X_{jk}^A - \frac{s}{T}U_k\right) + t\left(\sum_{j=s+1}^{T} X_{jk}^\tilde{P} - \frac{T-s}{T}U_k\right))\right]$$

$$= \min_{t>0} \left[ \phi_k^*(t) \exp(t\left(\sum_{j=1}^{T} (X_{jk}^\tilde{P} - \mathbb{E}[X_{jk}^\tilde{P}]) + \frac{T-s}{T}t\mathbb{E}[X_{jk}^\tilde{P}] - U_k\right))\right]$$

$$\leq \min_{t>0} \left[ \phi_k^*(t) \exp((T-s)\frac{\sigma^2}{\bar{a}_k}(e^{t\bar{a}_k} - 1 - t\bar{a}_k) + \frac{(T-s)t\varepsilon U_k}{\bar{a}_k})\right]$$

$$\leq \min_{t>0} \left[ \phi_k^*(t) \exp\left(\frac{T-s}{\bar{a}_k}(e^{t\bar{a}_k} - 1 - t\bar{a}_k - t\varepsilon - \frac{T-s}{\bar{a}_k})\right)\right]$$

$$\leq \left[ \phi_k^*(t) \exp\left(-\frac{(1-\varepsilon)(T-s)U_k}{\bar{a}_k}\right)\right]$$

$$\leq \left[ \phi_k^*(t) \exp\left(-\frac{T-s}{\bar{a}_k}\frac{\varepsilon^2}{2\gamma(1-\frac{\varepsilon}{2})}\right)\right]$$

where the first inequality follows from $\mathbb{E}(\sum_{j=1}^{s} X_{jk}^A + \sum_{j=s+1}^{T} X_{jk}^\tilde{P} - U_k) \geq 1$ when $\sum_{j=1}^{s} X_{jk}^A + \sum_{j=s+1}^{T} X_{jk}^\tilde{P} \geq U_k$; in the second equality, we set $\phi_k^*(t) = \mathbb{E}(\sum_{j=1}^{s} X_{jk}^\tilde{P} - \mathbb{E}[X_{jk}^\tilde{P}])$; the second inequality from Lemma 3.1 and $\mathbb{E}[X_{jk}^\tilde{P}] \leq (1-\varepsilon)U_k$; the third inequality from $\sigma^2 = \text{Var}(X_{jk}^\tilde{P}) \leq (1-\varepsilon)a_kU_k$; in the fourth inequality, we set $t = \frac{\ln(1-\varepsilon)}{\bar{a}_k}, \eta = \frac{\varepsilon}{1-\varepsilon}$; then the last inequality from $(1+\eta)\ln(1+\eta) - \eta \geq \frac{\eta^2}{1-2\frac{\varepsilon^2}{T}}$ and the definition of $\gamma$.

Next, for the bad event $G^s_2$, we have

$$P\left(\sum_{j=1}^{s} X_{jk}^A + \sum_{j=s+1}^{T} X_{jk}^\tilde{P} \leq L_k\right)$$

$$\leq \min_{t>0} \mathbb{E}\left[ \exp(t(L_k - \sum_{j=1}^{s} X_{jk}^A - \sum_{j=s+1}^{T} X_{jk}^\tilde{P}))\right]$$

$$= \min_{t>0} \mathbb{E}\left[ \exp(t\left(L_k - \sum_{j=1}^{s} X_{jk}^A - \frac{T-s}{T}L_k - \sum_{j=s+1}^{T} X_{jk}^\tilde{P}\right))\right]$$

$$= \min_{t>0} \left[ \phi_k^*(t) \exp(t\left(\sum_{j=1}^{T} (X_{jk}^\tilde{P} - \mathbb{E}[X_{jk}^\tilde{P}]) - (T-s)L_k\right))\right]$$

$$\leq \min_{t>0} \left[ \phi_k^*(t) \exp\left(-\frac{(1-\varepsilon)(T-s)(L_k - \mathbb{E}[X_{jk}^\tilde{P}])}{\bar{a}_k}\right)\right]$$

$$\leq \left[ \phi_k^*(t) \exp\left(-\frac{T-s}{\bar{a}_k}\frac{\varepsilon^2}{2\gamma(1-\frac{\varepsilon}{2})}\right)\right]$$
where in the second equality, we set $\varphi_k^s(t) = \exp(t \left( \frac{2}{T} L_k - \sum_{j=1}^s X_{jk} \right))$; the second inequality from Lemma B.1 and $TE[X_{jk}^s] \geq (1 - \varepsilon)L_k + \varepsilon \tilde{a}k$; the third inequality from $\sigma^2 = Var(X_{jk}^s) = Var(\tilde{a}k - X_{jk}^s) \leq \tilde{a}k E[a_k - X_{jk}^s] \leq \tilde{a}k (1-\varepsilon)(\tilde{T}a_k - L_k)$; in the fourth inequality, we set $t = \frac{-\ln(1-\varepsilon)}{\tilde{a}k}, \eta = \frac{\varepsilon}{1-\varepsilon}$; The last inequality from $(1+a) \ln(1+a) - a \geq \frac{a^2}{2} + \frac{a^3}{3}$ and the definition of $\gamma$.

Finally, we bound the probability of event $G_3^*$ by

$$P \left( \sum_{j=1}^s Y_j^s + \sum_{j=s+1}^T Y_j^\bar{F} \leq (1 - 2\varepsilon)W_\tau \right)$$

$$\leq \min_{t > 0} E \left[ \exp(t((1 - 2\varepsilon)W_\tau - \sum_{j=1}^s Y_j^s - \sum_{j=s+1}^T Y_j^\bar{F})) \right]$$

$$= \min_{t > 0} E \left[ \exp(t \left( \frac{2}{T} (1 - 2\varepsilon)W_\tau - \sum_{j=1}^s Y_j^s + t \left( \frac{T - s}{T} (1 - 2\varepsilon)W_\tau - \sum_{j=s+1}^T Y_j^\bar{F}) \right) \right]$$

$$= \min_{t > 0} E \left[ \psi^s(t) \exp(t \sum_{j=s+1}^T (E[Y_j^\bar{F}] - Y_j^\bar{F}) + \frac{T - s}{T} t((1 - 2\varepsilon)W_\tau - TE[Y_j^\bar{F}]) \right]$$

$$\leq \min_{t > 0} E \left[ \psi^s(t) \exp((T - s) \frac{2}{T} \left( e^{\tau \bar{w}} - 1 - t\bar{w} \right) + \frac{(1 - 2\varepsilon)W_\tau}{T} \right]$$

$$\leq \min_{t > 0} E \left[ \psi^s\left( \frac{-\ln(1 - \varepsilon)}{\bar{w}} \right) \exp(- \frac{(1 - \varepsilon)(T - s)W_\tau}{T \bar{w}} ((1 + \eta) \ln(1 + \eta) - \eta)) \right]$$

$$\leq \left[ \psi^s\left( \frac{-\ln(1 - \varepsilon)}{\bar{w}} \right) \exp(- \frac{T - s}{T} \frac{\varepsilon^2}{2(1 - \frac{2}{3}\varepsilon)\gamma} \right]$$

where in the second equality, we set $\psi^s(t) = \exp(t \left( \frac{2}{T} (1 - 2\varepsilon)W_\tau - \sum_{j=1}^s Y_j^s \right))$; the second inequality from Lemma B.1 and $TE[Y_j^\bar{F}] = (1 - \varepsilon)W_\tau$; the third inequality from $\sigma^2 = Var(Y_j^\bar{F}) \leq \bar{w}E[Y_j^\bar{F}] \leq \frac{(1 - 2\varepsilon)W_\tau}{T} \tilde{a}k$; in the fourth inequality, we set $t = \frac{-\ln(1-\varepsilon)}{\bar{w}}, \eta = \frac{\varepsilon}{1-\varepsilon}$. The last inequality from $(1 + \eta) \ln(1 + \eta) - \eta \geq \frac{\eta^2}{2 + \frac{1}{3}\eta}$ and the definition of $\gamma$.

With the inequalities (18)-(20) and union bound in probability theory, we can show that $P(G^c) \leq F(A^s P^{T-s})$ where $F(A^s P^{T-s})$ is defined by

$$F(A^s P^{T-s}) = E \left[ \sum_{k \in K} \phi_k^s \left( \frac{-\ln(1 - \varepsilon)}{a_k} \right) \exp(- \frac{T - s}{T} \frac{\varepsilon^2}{2(1 - \frac{2}{3}\varepsilon)\gamma} \right] + \sum_{k \in K} \psi^s_k \left( \frac{-\ln(1 - \varepsilon)}{\bar{w}} \right) \exp(- \frac{T - s}{T} \frac{\varepsilon^2}{2(1 - \frac{2}{3}\varepsilon)\gamma} \right]$$

In Lemma 4.1 we have proven that $F(P^T) = (2K + 1) \exp \left( -\frac{\varepsilon^2}{2(1 - \frac{2}{3}\varepsilon)\gamma} \right) \leq \varepsilon$, and we will show that $F(A^s P^{T-s}) \leq F(A^{s+1} P^{T-s+1})$ in the Lemma F.1. Thus, we have that $F(A^T) \leq F(P^T) \leq \varepsilon$ by induction. Substituting $\tau = \frac{\varepsilon}{1-\varepsilon}$ and $W_\tau \geq (1 - \frac{\varepsilon}{3})W_0$ in Theorem 4.3 we complete the proof of Theorem 4.4.

Lemma F.1. $F(A^s P^{T-s}) \leq F(A^{s+1} P^{T-s+1})$
According to algorithm A in Algorithm 2, we allocate the $s$-th request to the channel $i^*$ where

$$i^* = \arg \min_{i \in \mathcal{I}} \sum_{k \in \mathcal{K}} \phi_k^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{a}_k}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{a}_k})(X_{sk}^\bar{p} - \frac{U_k}{T}))$$

which means that

$$\mathcal{F}(A^s \bar{P}^{T-s}) \leq \left[ \sum_{k \in \mathcal{K}} \phi_k^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{a}_k}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{a}_k})(X_{sk}^\bar{p} - \frac{U_k}{T})) \right]$$

$$+ \sum_{k \in \mathcal{K}} \varphi_k^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{a}_k}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{a}_k})(\frac{L_k}{T} - X_{sk}^\bar{p}))$$

$$+ \psi^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{w}}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{w}})((1-\varepsilon)\hat{W} - \hat{Y}_s^\bar{p})) \right] \exp(-\frac{T-s}{T} \frac{\varepsilon^2}{2(1-\frac{2}{3}\varepsilon)}).$$

According to algorithm A in Algorithm 2, we allocate the $s$-th request to the channel $i^*$ where

$$i^* = \arg \min_{i \in \mathcal{I}} \sum_{k \in \mathcal{K}} \phi_k^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{a}_k}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{a}_k})(a_{sk} - \frac{U_k}{T}))$$

$$+ \sum_{k \in \mathcal{K}} \varphi_k^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{a}_k}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{a}_k})(\frac{L_k}{T} - a_{sk}))$$

$$+ \psi^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{w}}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{w}})((1-2\varepsilon)\hat{W} - \hat{w}_s))$$

which means that

$$\mathcal{F}(A^s \bar{P}^{T-s}) \leq \left[ \sum_{k \in \mathcal{K}} \phi_k^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{a}_k}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{a}_k})(X_{sk}^\bar{p} - \frac{U_k}{T})) \right]$$

$$+ \sum_{k \in \mathcal{K}} \varphi_k^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{a}_k}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{a}_k})(\frac{L_k}{T} - X_{sk}^\bar{p}))$$

$$+ \psi^{s-1}(\frac{-\ln(1-\varepsilon)}{\bar{w}}) \exp((-\frac{\ln(1-\varepsilon)}{\bar{w}})((1-2\varepsilon)\hat{W} - \hat{Y}_s^\bar{p})) \right] \exp(-\frac{T-s}{T} \frac{\varepsilon^2}{2(1-\frac{2}{3}\varepsilon)}).$$

For the term $\mathcal{F}$, we have

$$\mathcal{F} = \left[ \exp(-\frac{\ln(1-\varepsilon)}{\bar{a}_k})(X_{sk}^\bar{p} - \frac{U_k}{T}) \right]$$

$$\leq \exp(-\frac{\sigma^2}{\bar{a}_k} e^{\ln(1-\varepsilon)} - 1 + \ln(1-\varepsilon) + \frac{\varepsilon U_k}{T \bar{a}_k} \ln(1-\varepsilon))$$

$$\leq \exp\left( (1-\varepsilon) \frac{U_k}{T \bar{a}_k} \left( \frac{1}{1-\varepsilon} - 1 + \ln(1-\varepsilon) + \frac{\varepsilon}{1-\varepsilon} \ln(1-\varepsilon) \right) \right)$$

$$= \exp\left( -\frac{(1-\varepsilon) U_k}{T \bar{a}_k} \left( (1+\eta) \ln(1+\eta) - \eta \right) \right)$$

$$\leq \exp\left( -\frac{1}{T} \frac{\sigma^2}{2(1-\frac{2}{3}\varepsilon)} \right)$$

where the first inequality follows from Lemma B.1 and $\mathbb{E}[X_{sk}^\bar{p}] \leq (1-\varepsilon)U_k/T$, the second from $\sigma^2 = \text{Var}(X_{sk}^\bar{p}) \leq \frac{(1-\varepsilon)U_k}{T \bar{a}_k}$. Next setting $\eta = \frac{\varepsilon}{1-\varepsilon}$, the last inequality follows from $(1+\eta) \ln(1+\eta) - \eta \geq \frac{\eta^2}{2(1+\eta)}$ and the definition of $\gamma$. 

For the term $\mathcal{2}$, we have
\[
\mathcal{2} = \mathbb{E} \left[ \exp \left( -\frac{\ln(1-\epsilon)}{\bar{a}_k} \left( (\mathbb{E}[X_{sk}] - X_{sk}^\ast) + \frac{L_k}{T} \mathbb{E}[X_{sk}] \right) \right) \right] \\
\leq \mathbb{E} \left[ \exp \left( \frac{\sigma^2}{\bar{a}_k^2} \left( e^{-\ln(1-\epsilon)} - 1 + \ln(1-\epsilon) \right) + \frac{\epsilon(T\bar{a}_k - L_k)}{T\bar{a}_k} \ln(1-\epsilon) \right) \right] \\
\leq \mathbb{E} \left[ \exp \left( \frac{(1-\epsilon)(T\bar{a}_k - L_k)}{T\bar{a}_k} \left( \frac{1}{1-\epsilon} - 1 + \ln(1-\epsilon) + \frac{\epsilon}{1-\epsilon} \ln(1-\epsilon) \right) \right) \right] \\
= \mathbb{E} \left[ \exp \left( -\frac{(1-\epsilon)(T\bar{a}_k - L_k)}{T\bar{a}_k} \left( (1+\eta) \ln(1+\eta) - \eta \right) \right) \right] \\
\leq \exp \left( -\frac{1}{T} \frac{\epsilon^2}{2(1-\frac{2}{3}\epsilon)} \right)
\]
derivation{where the first inequality follows from Lemma B.1 and $\mathbb{E}[X_{sk}] \leq \frac{(1-\epsilon)L_k + \epsilon T \bar{a}_k}{T}$, the second from $\sigma^2 = Var(X_{sk}) \leq \bar{a}_k \frac{(1-\epsilon)(T\bar{a}_k - L_k)}{T}$. Next setting $\eta = \frac{1}{1-\epsilon}$, the last inequality follows from $(1+\eta) \ln(1+\eta) - \eta \geq \frac{\eta^2}{2+\frac{4}{3}\epsilon}$ and the definition of $\gamma$.}

For the term $\mathcal{3}$, we have
\[
\mathcal{3} = \mathbb{E} \left[ \exp \left( -\frac{\ln(1-\epsilon)}{\bar{w}} \left( (\mathbb{E}[Y_{s}] - Y_{s}^\ast) + \frac{(1-2\epsilon)\bar{w}}{T} \mathbb{E}[Y_{s}] \right) \right) \right] \\
\leq \mathbb{E} \left[ \exp \left( \frac{\sigma_1^2}{\bar{w}^2} \left( e^{-\ln(1-\epsilon)} - 1 + \ln(1-\epsilon) \right) + \frac{\epsilon\bar{w}}{T\bar{w}} \ln(1-\epsilon) \right) \right] \\
\leq \mathbb{E} \left[ \exp \left( \frac{(1-\epsilon)\bar{w}}{T\bar{w}} \left( \frac{1}{1-\epsilon} - 1 + \ln(1-\epsilon) + \frac{\epsilon}{1-\epsilon} \ln(1-\epsilon) \right) \right) \right] \\
= \mathbb{E} \left[ \exp \left( -\frac{(1-\epsilon)\bar{w}}{T\bar{w}} \left( (1+\eta) \ln(1+\eta) - \eta \right) \right) \right] \\
\leq \exp \left( -\frac{1}{T} \frac{\epsilon^2}{2(1-\frac{2}{3}\epsilon)} \right)
\]
derivation{where the first inequality follows from Lemma B.1 and $\mathbb{E}[Y_{s}] = \frac{(1-\epsilon)\bar{w}}{T}$, the second from $\sigma_1^2 = Var(Y_{s}) \leq \bar{w} \frac{(1-\epsilon)\bar{w}}{T}$, Next setting $\eta = \frac{1}{1-\epsilon}$, the last inequality follows from $(1+\eta) \ln(1+\eta) - \eta \geq \frac{\eta^2}{2+\frac{4}{3}\epsilon}$ and the definition of $\gamma$. According to the inequality (24), (26), we can show that
\[
\mathcal{F}(A^s\bar{P}^{T-s}) \leq \mathbb{E} \left[ \sum_{k \in K} \phi_k^{s-1} \left( -\frac{\ln(1-\epsilon)}{\bar{a}_k} \right) + \sum_{k \in K} \psi_k^{s-1} \left( -\frac{\ln(1-\epsilon)}{\bar{w}} \right) \right] \exp \left( -\frac{T-s+1}{T} \frac{\epsilon^2}{2(1-\frac{2}{3}\epsilon)} \right)
\]
which completes the proof.}

\section*{G. Proof of Theorem 4.5}

\subsection*{G.1. Concentration of $Z^r$}

In the first step, we study the relationship between $Z^r$ and $W_{\epsilon}$.

\begin{lemma}
Under Assumption 1, if $\tau_1 + \epsilon \leq \xi^*$ and $\gamma_1 = \max \left( \frac{\bar{a}_k}{\bar{w}_k}, \frac{\bar{a}_k}{(1-\epsilon)T\bar{a}_k - L_k}, \frac{\bar{w}}{w_{\epsilon+\tau_1}} \right) = O \left( \frac{\epsilon^2}{m(\kappa/\epsilon)} \right)$, for given measure of feasibility $\xi^*$, we have
\[
W^r \leq \frac{T \bar{w} \bar{w}_{\epsilon+\tau_1}}{2} \left( 1 + (2 + \frac{1}{\xi^*-\epsilon}) \varepsilon_{x,r} \right)
\]
with probability at least $1 - \delta$, where the predefined parameter $\epsilon > 0$, $\tau_1 = \frac{\varepsilon_{x,r}^2 \delta}{m}$, $l = \log_2 \left( \frac{1}{\delta} \right)$ and $\varepsilon_{x,r} = \frac{\varepsilon_{x,r}^2 \delta}{m}$.
\end{lemma}
We have divided the equation (31) into three parts. Next, we will derive the relationship between

\[ W^r = \max_x \sum_{i \in I, j \in S_r} w_{ij} x_{ij} \]

subject to

\[ \frac{t_r}{T} (L_k + \varepsilon T \bar{a}_k) \leq \sum_{i \in I, j \in S_r} a_{ijk} x_{ij} \leq \frac{t_r}{T} U_k, \forall k \in \mathcal{K} \]

\[ \sum_{i \in I} x_{ij} \leq 1, \forall j \in S_r \]

\[ x_{ij} \geq 0, \forall i \in I, j \in S_r \]

where we use \( S_r \) to denote the request set in stage \( r \). The dual of LP (28) is

\[ W^r = \min_{\alpha, \beta, \rho} \sum_{k \in \mathcal{K}} \alpha_k T U_k - \sum_{k \in \mathcal{K}} \beta_k \left( T (L_k + \varepsilon T \bar{a}_k) + \sum_{j \in S_r} \rho_j \right) \]

subject to

\[ (\alpha_k - \beta_k) a_{ijk} - w_{ij} + \rho_j \geq 0 \forall i \in I, j \in S_r \]

\[ \alpha_k, \beta_k, \rho_j \geq 0, k \in \mathcal{K}, j \in S_r \]

Comparing to the dual of LP (28) with the dual of problem \( E(\varepsilon) \), which is

\[ \min_{\alpha, \beta, \rho} \sum_{k \in \mathcal{K}} \alpha_k U_k - \sum_{k \in \mathcal{K}} \beta_k \left( T (L_k + \varepsilon T \bar{a}_k) + \sum_{j \in \mathcal{J}} T p_j \rho_j \right) \]

subject to

\[ (\alpha_k - \beta_k) a_{ijk} - w_{ij} + \rho_j \geq 0 \forall i \in I, j \in \mathcal{J} \]

\[ \alpha_k, \beta_k, \rho_j \geq 0, k \in \mathcal{K}, j \in \mathcal{J} \]

we can observe that the constraints of LP (29) is a subset of those of LP (30). We denote the primal and dual optimal solution of \( E(\varepsilon) \) as \( \{x^*_i\} \) and \( \{\alpha^*_k, \beta^*_k, \rho^*_k\} \). So \( \{\alpha^*_k, \beta^*_k, \rho^*_k\} \) is feasible for LP (29).

Hence,

\[ W^r \leq \sum_{k \in \mathcal{K}} \alpha^*_k \frac{t_r}{T} U_k - \sum_{k \in \mathcal{K}} \beta^*_k \frac{t_r}{T} \left( L_k + \varepsilon T \bar{a}_k \right) + \sum_{j \in S_r} \rho^*_j \]

\[ = \sum_{k \in \mathcal{K}} \alpha^*_k \left( \frac{t_r}{T} U_k - \sum_{j \in S_r, i \in I} a_{ijk} x^*_i \right) + \sum_{k \in \mathcal{K}} \beta^*_k \left( \sum_{j \in S_r, i \in I} a_{ijk} x^*_i - \frac{t_r}{T} \left( L_k + \varepsilon T \bar{a}_k \right) \right) \]

\[ + \sum_{j \in S_r} \rho^*_j + \sum_{i \in I, k \in \mathcal{K}} (\alpha^*_k - \beta^*_k) a_{ijk} x^*_i \]

We have divided the equation (31) into three parts. Next, we will derive the relationship between \( W^r \) and \( W^r \) by controlling these three parts. To facilitate the analysis, we first present the KKT conditions (Boyd et al., 2004) for the problem \( E(\varepsilon) \) as follows

\[ \sum_{k \in \mathcal{K}} (\alpha^*_k - \beta^*_k) a_{ijk} x^*_i - w_{ij} x^*_i + \rho^*_j x^*_i = 0, \forall i \in I, j \in S_r \]

\[ \rho^*_j (x^*_i - 1) = 0, \forall j \in S_r \]

\[ \alpha^*_k \left( \sum_{i \in I} T p_j a_{ijk} x^*_i - U_k \right) = 0, \forall k \in \mathcal{K} \]

\[ \beta^*_k \left( L_k + \varepsilon T \bar{a}_k - \sum_{i \in I} T p_j a_{ijk} x^*_i \right) = 0, \forall k \in \mathcal{K} \]
Nearly Optimal Competitive Ratio for Online Allocation Problems with Two-sided Resource Constraints and Finite Requests

For part 1, according to the KKT conditions, if \( \sum_{i \in I, j \in J} Tp_j a_{ijk} x_{ij}^* < U_k \), then \( \alpha_k^* = 0 \). Thus we only consider the resource \( k \) making \( \sum_{i \in I, j \in J} Tp_j a_{ijk} x_{ij}^* = U_k \). According to the Assumption 1, we have \( \mathbb{E}(\sum_{j \in S, i \in I} a_{ijk} x_{ij}^*) = \frac{t_r}{T} U_k \) for all \( j \in S_r \). Thus, we can show that

\[
P \left( \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* \leq (1 - \varepsilon_{x,r}) \frac{t_r}{T} U_k \right)
\]

\[
= P \left( \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* - \mathbb{E} \left[ \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* \right] \leq - \varepsilon_{x,r} \frac{t_r}{T} U_k \right)
\]

\[
\leq \exp \left( - \frac{t_r^2 \varepsilon_{x,r}^2}{2(1 + \frac{t_r}{T})} \right)
\]

\[
\leq \exp \left( - \frac{t_r^2 \varepsilon_{x,r}^2}{2(1 + \frac{t_r}{T})^2} \right)
\]

\[
\leq \frac{\delta}{2K + 1}
\]

where the first inequality follows from the Bernstein inequality in Lemma 1, the second inequality from the definition of \( \varepsilon_{x,r} \), the third inequality from the definition of \( \gamma_1 \) and the last from the definition of \( \varepsilon_{x,r} \).

For part 2, we only consider the \( k \) making \( \sum_{i \in I, j \in J} Tp_j a_{ijk} x_{ij}^* = L_k + \varepsilon T \tilde{a}_k \), which means \( \mathbb{E} \left[ \sum_{j \in S, i \in I} (\tilde{a}_k - a_{ijk} x_{ij}^*) \right] = \frac{t_r}{T} \left( 1 - \varepsilon \right) T \tilde{a}_k - L_k \). Using Bernstein inequality, we have

\[
P \left( \sum_{j \in S_r, i \in I} (\tilde{a}_k - a_{ijk} x_{ij}^*) \leq (1 - \varepsilon_{x,r}) \frac{t_r}{T} ((1 - \varepsilon) T \tilde{a}_k - L_k) \right)
\]

\[
= P \left( \sum_{j \in S_r, i \in I} (\tilde{a}_k - a_{ijk} x_{ij}^*) - \mathbb{E} \left[ \sum_{j \in S_r, i \in I} (\tilde{a}_k - a_{ijk} x_{ij}^*) \right] \leq - \varepsilon_{x,r} \frac{t_r}{T} ((1 - \varepsilon) T \tilde{a}_k - L_k) \right)
\]

\[
\leq \exp \left( - \frac{t_r^2 \varepsilon_{x,r}^2}{2(1 - \varepsilon) T \tilde{a}_k - L_k} \right)
\]

\[
\leq \exp \left( - \frac{t_r^2 \varepsilon_{x,r}^2}{2(1 - \varepsilon) T \tilde{a}_k - L_k} \right)
\]

\[
\leq \frac{\delta}{2K + 1}
\]

where the second inequality from \( \text{Var} \left( \sum_{j \in S, i \in I} (\tilde{a}_k - a_{ijk} x_{ij}^*) \right) / t_r \leq \tilde{a}_k \mathbb{E} \left[ \sum_{j \in S, i \in I} (\tilde{a}_k - a_{ijk} x_{ij}^*) \right] / t_r = \tilde{a}_k \frac{(1 - \varepsilon) T \tilde{a}_k - L_k}{T} \), the third inequality from the definition of \( \gamma_1 \) and the last from the definition of \( \varepsilon_{x,r} \).

For the last part 3, from KKT conditions, it’s easy to verify that \( \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* = \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) w_{ij} x_{ij}^* = 0 \), so \( \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* + \rho_j^* \sum_{i \in I} x_{ij}^* = \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* - \sum_{i \in I} w_{ij} x_{ij}^* + \rho_j^* = 0 \), so \( \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* + \rho_j^* \sum_{i \in I} x_{ij}^* = \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* + \rho_j^* \sum_{i \in I} w_{ij} x_{ij}^* = 0 \) for all \( j \in S_r \). Therefore, following the
where the first inequality follows from the Bernstein inequality in Lemma [B.1], the second inequality from
regard the problem

Based on inequality (32)-(34), we have shown that the following inequalities holds with probability at least

where the first inequality follows from the Bernstein inequality in Lemma [B.1] the second inequality from

the third inequality from the definition of $\gamma_1$ and the last from the definition of $\varepsilon_{x,r}$. 

Based on inequality (32)-(34), we have shown that the following inequalities holds with probability at least $1 - \delta$

Therefore, with probability at least $1 - \delta$, we have

where the first inequality from $\sum_{j \in S_r,i \in I} a_{ij} x_{ij}^* \geq (1 - \varepsilon_{x,r}) \frac{t_r}{T} U_k$, $\forall k \in K$; the second inequality from

from $W_c = \sum_{k \in K} \alpha_k^* U_k - \sum_{k \in K} \beta_k^* (L_k + \varepsilon T \bar{a}_k) + \sum_{j \in S_r,i \in I} \beta_k^* t_r \rho_j^* \geq \sum_{k \in K} \alpha_k^* U_k - \sum_{k \in K} \beta_k^* (\varepsilon T \bar{a}_k + L_k)$; the final inequality from $\sum_{k \in K} \beta_k^* T \bar{a}_k \leq \frac{1}{\varepsilon} W_c$, which can be shown if we follow the proof of Theorem 4.2 in Appendix D and
regard the problem $E(\varepsilon)$ as an LP with $\xi^*$ as a measure of feasibility.

\[ \textbf{Theorem G.2.} \text{ Under Assumption 13 if } \tau_1 + \varepsilon \leq \xi^* \text{ and } \gamma_1 = \max \left( \frac{\bar{a}_k}{L_k}, \frac{\bar{a}_k}{(1 - r) U_k - L_k}, \frac{\bar{w}}{W_c + 1} \right) = O \left( \frac{\varepsilon^2}{\ln(1/\varepsilon)} \right), \text{ with} \]
probability $1 - 2\delta$, we have
\[
\frac{t_r W_\varepsilon}{T} \left(1 - (2 + \frac{1}{\xi^* - \varepsilon})\varepsilon_{x,r}\right) \leq W^r \leq \frac{t_r W_\varepsilon}{T} \left(1 + (2 + \frac{1}{\xi^* - \varepsilon})\varepsilon_{x,r}\right)
\]
where the predefined parameter $\varepsilon > 0$, $\tau_1 = \frac{\sqrt{r}}{1 - \sqrt{r}}$, $\delta = \frac{\varepsilon}{\xi^*}$, $l = \log_2(\frac{1}{\varepsilon})$ and $\varepsilon_{x,r} = \sqrt{\frac{4T\gamma_1 \ln(\frac{2r+1}{\varepsilon})}{t_r\gamma_1}}$.

**Proof.** RHS: we have proven the right hand side in Lemma G.1. LHS: For every request in stage $r$, we consider to imitate Algorithm 1 to design an algorithm $\tilde{P}_1$. In Algorithm $\tilde{P}_1$, we first solve the LP problem $E(\varepsilon + \frac{\varepsilon_{x,r}}{1 - \varepsilon_{x,r}})$ to get the LP solution $x_{ij}^1$* and then assign request $j \in J$ to channel $i \in I$ with probability $(1 - \varepsilon_{x,r})x_{ij}^1$* . Following the similar analysis in the proof of Lemma 4.1, we can prove that, with probability $1 - \delta$,
\[
P\left(\sum_{j=1}^{t_r} X_{jk}^\tilde{P}_1 \geq t_r U_k / T\right) \leq \exp\left(- \frac{t_r \varepsilon_{x,r}^2}{2(1 - 2\varepsilon_{x,r})T^\varepsilon_{x,r}}\right)
\]
\[
P\left(\sum_{j=1}^{t_r} Y_j^\tilde{P}_1 \leq (1 - (2 + \frac{1}{\xi^* - \varepsilon})\varepsilon_{x,r}) \frac{t_r}{T} W_\varepsilon\right) \leq \exp\left(- \frac{t_r \varepsilon_{x,r}^2}{2(1 - 2\varepsilon_{x,r})T^\varepsilon_{x,r}}\right)
\]
\[
P\left(\sum_{j=1}^{t_r} X_{jk}^\tilde{P}_1 \geq t_r L_k / T\right) \leq \exp\left(- \frac{t_r \varepsilon_{x,r}^2}{2(1 - 2\varepsilon_{x,r})T^\varepsilon_{x,r}}\right)
\]
where the second inequality from the truth that the problem $E(\varepsilon)$ is satisfied with the strong feasible condition with the measure parameter $\xi^* - \varepsilon$ and $W_{\varepsilon_{x,r}+\varepsilon} \geq W_{\tau_1+\varepsilon}$. Therefore, we have that
\[
P\left(\sum_{j=1}^{t_r} Y_j^\tilde{P}_1 \leq (1 - (2 + \frac{1}{\xi^* - \varepsilon})\varepsilon_{x,r}) \frac{t_r}{T} W_\varepsilon\right) + \sum_{k \in K} \frac{t_r}{T} L_k \leq (2K + 1) \exp\left(- \frac{t_r \varepsilon_{x,r}^2}{4T\gamma_1}\right) 
\]
\[
\leq \delta,
\]
which means that $W^r \geq (1 - (2 + \frac{1}{\xi^* - \varepsilon})\varepsilon_{x,r}) \frac{t_r}{T} W_\varepsilon$, w.p. $1 - \delta$. This completes the proof. $\square$

**G.2. Proof with $\xi^*$ but without the Knowledge of Distribution**

**Theorem 4.5.** Under Assumption 3 if $\varepsilon > 0$, $\tau_1 = \frac{\sqrt{r}}{1 - \sqrt{r}}$ such that $\tau_1 + \varepsilon \leq \xi^*$ and $\gamma_1 = \max(\frac{\bar{a}}{t_r\gamma_1}, \frac{\mu}{(1 - \varepsilon_{x,r})T^\varepsilon_{x,r}}) = O\left(\frac{\varepsilon_{x,r}^2}{\xi^* - \varepsilon}\right)$. Algorithm 1 defined in Algorithm 4 achieves an objective value of at least $(1 - O\left(\frac{\varepsilon_{x,r}}{\xi^* - \varepsilon}\right)) W_0$ and satisfies the constraints w.p. $1 - \varepsilon$.

Now, we prove that, at each stage $r$, Algorithm $A_1$ returns a solution whose cumulative revenue is at least $\frac{t_r}{T} Z_r (1 - \varepsilon_{y,r})$. Meanwhile, the consumed amount of every resource $k$ is between $\frac{t_r}{T} (L_k + (\varepsilon - \varepsilon_{x,r} \varepsilon_{x,r}) T a_k) (1 + \varepsilon_{x,r})$ and $\frac{t_r}{T} L_k (1 + \varepsilon_{x,r})$ with probability at least $1 - \delta$.

**First step:** We design a surrogate Algorithm $\tilde{P}_2$ that allocates request $j$ to channel $i$ with probability $x(\varepsilon)^{\tilde{P}_2}_{ij}$.

**Lemma G.3.** In the $r$-th stage, if $\gamma_1 = O\left(\frac{\varepsilon_{x,r}^2}{\ln(\frac{2r+1}{\varepsilon})}\right)$ and $Z_r \leq W_\varepsilon$, the Algorithm $\tilde{P}_2$ returns a solution satisfying the $\sum_{j=1}^{t_r+1} Y_j^\tilde{P}_2 \geq (1 - \varepsilon_{x,r}) \frac{t_r}{T} Z_r$ and $\sum_{j=1}^{t_r+1} X_j^\tilde{P}_2 \geq \left[\frac{\ln(\frac{2r+1}{\varepsilon})}{t_r\gamma_1} \right] \left[\frac{t_r}{2} ((1 + \varepsilon_{x,r}) L_k + (1 + \varepsilon_{x,r} - \varepsilon_{x,r}) T a_k) (1 + \varepsilon_{y,r}) \right]$ w.p. $1 - \delta$, where $\delta = \frac{\varepsilon}{\xi^*}$, $\varepsilon_{x,r} = \sqrt{\frac{4T\gamma_1 \ln(\frac{2r+1}{\varepsilon})}{t_r\gamma_1}}$, and $\varepsilon_{y,r} = \sqrt{\frac{4T\gamma_1 \ln(\frac{2r+1}{\varepsilon})}{2z_t r}}$.

**Proof.** Following the same technique in the proof of Lemma G.1, we use Bernstein inequality to bound the probability of
upper bound violation as follows

\[
P \left( \sum_{j=t+1}^{t+1} X_{j,k}^{t} \geq (1 + \varepsilon_{x,r}) \frac{t_{r}}{T} U_{k} \right)
\]

\[
\leq \exp \left( - \frac{t_{r} \varepsilon_{x,r}^{2} U_{k}}{2(1 + \frac{\varepsilon_{x,r}^{2}}{3}) \gamma_{1}} \right)
\]

\[
\leq \exp \left( - \frac{t_{r} \varepsilon_{x,r}^{2}}{2(1 + \frac{\varepsilon_{x,r}}{3}) \gamma_{1}} \right)
\]

\[
\leq \frac{\delta}{2K + 1}.
\]

For the lower bound,

\[
P \left( \sum_{j=t+1}^{t+1} X_{j,k}^{t} \leq \frac{t_{r}}{T} (L_{k} + (\varepsilon - \frac{\varepsilon_{x,r}}{1 + \varepsilon_{x,r}}) T \bar{a}_{k} (1 + \varepsilon_{x,r}) \right)
\]

\[
= P \left( \sum_{j=t+1}^{t+1} (\bar{a}_{k} - X_{j,k}^{t}) \geq (1 + \varepsilon_{x,r}) \frac{t_{r}}{T} ((1 - \varepsilon) T \bar{a}_k - L_{k}) \right)
\]

\[
\leq \exp \left( - \frac{t_{r} \varepsilon_{x,r}^{2}}{2(1 + \frac{\varepsilon_{x,r}}{3}) \gamma_{1}} \right)
\]

\[
\leq \frac{\delta}{2K + 1}.
\]

For the accumulative revenue in \( r \)-th stage,

\[
P \left( \sum_{j=t+1}^{t+1} Y_{j}^{t} \leq (1 - \varepsilon_{y,r}) \frac{t_{r}}{T} Z^{r} \right)
\]

\[
= P \left( \sum_{j=t+1}^{t+1} \left( \mathbb{E}[Y_{j}^{t}] - Y_{j}^{t} \right) \geq \frac{t_{r}}{T} \left( \mathbb{E}[Y_{j}^{t}] - (1 - \varepsilon_{y,r}) Z^{r} \right) \right)
\]

\[
\leq \exp \left( - \frac{\left( \mathbb{E}[Y_{j}^{t}] - (1 - \varepsilon_{y,r}) Z^{r} \right)^{2} t_{r}}{T \left( 2T \sigma_{y}^{2} + \frac{2}{3} \bar{w} \left( \mathbb{E}[Y_{j}^{t}] - (1 - \varepsilon_{y,r}) Z^{r} \right) \right)} \right)
\]

\[
= \exp \left( - \frac{t_{r} \left( \mathbb{E}[Y_{j}^{t}] - (1 - \varepsilon_{y,r}) Z^{r} \right)^{2}}{2 \mathbb{E}[Y_{j}^{t}] - (1 - 2\varepsilon_{y,r}) Z^{r} + \frac{2}{3} \bar{w}} \right)
\]

\[
\leq \exp \left( - \frac{t_{r} \varepsilon_{y,r}^{2}}{2(1 + \frac{\varepsilon_{y,r}}{3}) T \frac{\bar{w}}{Z^{r}}} \right)
\]

\[
\leq \frac{\delta}{2K + 1}.
\]
where the second inequality follows $\sigma_1^2 = Var(Y_j^{\bar{P}_2}) \leq \bar{a}_k \mathbb{E}[Y_j^{\bar{P}_2}]$ and $T \mathbb{E}[Y_j^{\bar{P}_2}] - (1 - \varepsilon_{y,r}) Z^r \geq \varepsilon_{y,r} T \mathbb{E}[Y_j^{\bar{P}_2}]$, the third inequality follows $Z^r \leq W_{\varepsilon} = T \mathbb{E}[Y_j^{\bar{P}_2}]$ according to the condition of the lemma, and the last inequality from $\varepsilon_{y,r} = \sqrt{\frac{4T \ln \left( \frac{4T \ln (1 + \frac{1}{2})}{\bar{a}_k} \right) \bar{a}_k}{Z^r}}$. Therefore,

$$
\sum_{k \in \mathcal{K}} P \left( \sum_{j=1+t_r}^{s+t_r} X_{jk} \geq \frac{1 + \varepsilon_{x,r} t_r U_k}{T} \right) \\
\leq \min_{t > 0} \mathbb{E} \left[ \exp(t (\sum_{j=1+t_r}^{s+t_r} X_{jk} - \mathbb{E}[X_{jk}])] + t(\sum_{j=s+t_r}^{t_r} X_{jk} - \frac{1 + \varepsilon_{x,r} t_r U_k}{T}) \right] \\
\leq \min_{t > 0} \mathbb{E} \left[ \phi_k^s(t) \exp((t_r - s) \frac{Var(X_{jk})}{\bar{a}_k}(e^{\bar{a}_k t_r - 1} - t \bar{a}_k) + \frac{-(t_r - s) t \varepsilon_{x,r} U_k}{T}) \right] \\
\leq \mathbb{E} \left[ \phi_k^s \left( \frac{\ln(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp(-\frac{t_r - s}{T} \frac{\varepsilon_{x,r} U_k}{4 \bar{a}_k}) \right] \\
\leq \mathbb{E} \left[ \phi_k^s \left( \frac{\ln(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp(-\frac{t_r - s}{T} \frac{\varepsilon_{x,r}}{4 \gamma_1}) \right]
$$

where $\phi_k^s(t) = \exp(t (\sum_{j=1+t_r}^{s+t_r} X_{jk} - \mathbb{E}[X_{jk}])]$. It should be noted that most of the above analysis is similar as the derivation of inequality (18) except that $Var(X_{jk}^{\bar{P}_2}) \leq \bar{a}_k \mathbb{E}[X_{jk}^{\bar{P}_2}] \leq \bar{a}_k \frac{U_k}{T}$.

Next for the lower bound, we set $Z_{jk}^{\bar{P}_2} = \bar{a}_k - X_{jk}^{\bar{P}_2}$ and $Z_{jk}^{A_1} = \bar{a}_k - X_{jk}^{A_1}$, then we have

$$
P \left( \sum_{j=1+t_r}^{s+t_r} Z_{jk}^{A_1} + \sum_{j=s+t_r}^{t_r} Z_{jk}^{\bar{P}_2} \geq \frac{(1 + \varepsilon_{x,r}) t_r \left( 1 - \varepsilon \right) \bar{a}_k - L_k}{T} \right) \\
\leq \min_{t > 0} \mathbb{E} \left[ \exp((t (\sum_{j=1+t_r}^{s+t_r} Z_{jk}^{A_1} + \sum_{j=s+t_r}^{t_r} Z_{jk}^{\bar{P}_2} - \frac{(1 + \varepsilon_{x,r}) t_r \left( 1 - \varepsilon \right) \bar{a}_k - L_k}{T}) \right) \\
\leq \min_{t > 0} \mathbb{E} \left[ \exp(\sum_{j=1+t_r}^{s+t_r} Z_{jk}^{A_1} + \sum_{j=s+t_r}^{t_r} Z_{jk}^{\bar{P}_2} - \frac{(1 + \varepsilon_{x,r}) t_r \left( 1 - \varepsilon \right) \bar{a}_k - L_k}{T}) \right) \right]
$$

**Second Step:** Applying the same technique in the proof of Theorem 4.4, we derive a potential function to bound the failure probability of hybrid Algorithm $A_1^{\bar{P}_2} e^{-x}$ for request in stage $r$. We begin with the moment generating function for the event that the consumed resource $k \in \mathcal{K}$ is larger than $(1 + \varepsilon_{x,r}) \frac{U_k}{T}$.

It can be shown that

$$
P \left( \sum_{j=1+t_r}^{s+t_r} X_{jk}^{A_1} + \sum_{j=s+t_r}^{t_r} X_{jk}^{\bar{P}_2} \geq \frac{(1 + \varepsilon_{x,r}) t_r U_k}{T} \right) \\
\leq \min_{t > 0} \mathbb{E} \left[ \exp(t (\sum_{j=1+t_r}^{s+t_r} X_{jk}^{A_1} + \sum_{j=s+t_r}^{t_r} X_{jk}^{\bar{P}_2} - \frac{(1 + \varepsilon_{x,r}) t_r U_k}{T}) \right] \\
\leq \min_{t > 0} \mathbb{E} \left[ \exp(t (\sum_{j=1+t_r}^{s+t_r} X_{jk}^{A_1} - \mathbb{E}[X_{jk}^{\bar{P}_2}]) + t(\sum_{j=s+t_r}^{t_r} X_{jk}^{\bar{P}_2} - \frac{(1 + \varepsilon_{x,r}) t_r U_k}{T}) \right] \\
\leq \min_{t > 0} \mathbb{E} \left[ \phi_k^s(t) \exp((t_r - s) \frac{Var(X_{jk})}{\bar{a}_k}(e^{\bar{a}_k t_r - 1} - t \bar{a}_k) + \frac{-(t_r - s) t \varepsilon_{x,r} U_k}{T}) \right] \\
\leq \mathbb{E} \left[ \phi_k^s \left( \frac{\ln(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp(-\frac{t_r - s}{T} \frac{\varepsilon_{x,r} U_k}{4 \bar{a}_k}) \right] \\
\leq \mathbb{E} \left[ \phi_k^s \left( \frac{\ln(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp(-\frac{t_r - s}{T} \frac{\varepsilon_{x,r}}{4 \gamma_1}) \right]
$$
With the inequalities (40)-(42), we can bound the failure probability of hybrid Algorithm $\psi Z$

\[
\leq \min_{t > 0} \mathbb{E} \left[ \exp \left( t \left( \sum_{j=1+t_r}^{s+t_r} Z_{jk}^A - \frac{(1 + \varepsilon_{x,r})s}{T} (1 - \varepsilon) T \bar{a}_k - L_k \right) \right) \right]
\]

\[
+ t \left( \sum_{j=s+t_r}^{t_r-1} Z_{jk}^P - \frac{(1 + \varepsilon_{x,r})(t_r - s)}{T} \right) \left( (1 - \varepsilon) T \bar{a}_k - L_k \right) \right) \right) \right]
\]

\[
\leq \min_{t > 0} \mathbb{E} \left[ \frac{\varphi_k^* (t)}{a_k} \exp \left( t - s \frac{\sigma^2_k}{a_k^2} \right) \exp \left( - \frac{(t_r - s) (1 - \varepsilon) T \bar{a}_k - L_k}{T} \right) \right) \left( (1 + \eta) \ln(1 + \eta) - \eta \right) \right)
\]

\[
\leq \mathbb{E} \left[ \frac{\varphi_k^* (t)}{a_k} \exp \left( - \frac{(t_r - s) \varepsilon^2_{x,r}}{T} \right) \right) \left( (1 + \eta) \ln(1 + \eta) - \eta \right) \right]
\]

where the third inequality follows from setting $\varphi_k^* (t) = \exp \left( t \left( \sum_{j=1+t_r}^{s+t_r} Z_{jk}^A - \frac{(1 + \varepsilon_{x,r})s}{T} (1 - \varepsilon) T \bar{a}_k - L_k \right) \right)$; the fifth inequality from $\mathbb{E} [Z_{jk}^P] \leq (1 - \varepsilon) T \bar{a}_k - L_k$ and $\sigma^2 = \text{Var}(Z_{jk}^P) \leq \bar{a}_k \mathbb{E} [Z_{jk}^P]$.

Then we consider the revenue and have that

\[
P \left( \sum_{j=1+t_r}^{s+t_r} Y_{j}^{A_1} + \sum_{j=s+1+t_r}^{t_r+1} Y_{j}^{P_2} \leq (1 - \varepsilon_{y,r}) \frac{t_r}{T} Z_r \right)
\]

\[
\leq \min_{t > 0} \mathbb{E} \left[ \exp \left( t \left( (1 - \varepsilon_{y,r}) \frac{t_r}{T} Z_r - \sum_{j=1+t_r}^{s+t_r} Y_{j}^{A_1} - \sum_{j=s+1+t_r}^{t_r+1} Y_{j}^{P_2} \right) \right) \right]
\]

\[
\leq \min_{t > 0} \mathbb{E} \left[ \exp \left( t \left( \frac{s}{T} (1 - \varepsilon_{y,r}) Z_r - \sum_{j=1+t_r}^{s+t_r} Y_{j}^{A_1} + \frac{t_r - s}{T} - T Z_r - \sum_{j=s+1+t_r}^{t_r+1} Y_{j}^{P_2} \right) \right) \right]
\]

\[
\leq \min_{t > 0} \mathbb{E} \left[ \psi^* \left( t \sum_{j=s+1+t_r}^{t_r+1} Y_{j}^{P_2} - Y_{j}^{P_2} \right) + \frac{t_r - s}{T} - T \right) \left( (1 - \varepsilon_{y,r}) Z_r - \mathbb{E} [Y_{j}^{P_2}] \right) \right]
\]

\[
\leq \min_{t > 0} \mathbb{E} \left[ \psi^* \left( t \left( \frac{\varepsilon^2_{y,r}}{\bar{w}^2} (t \bar{w} - 1 - t \bar{w}) - (t_r - s) \varepsilon_{y,r} \mathbb{E} [Y_{j}^{P_2}] \right) \right) \right]
\]

\[
\leq \mathbb{E} \left[ \psi^* \left( \frac{\ln(1 + \varepsilon_{y,r})}{\bar{w}} \right) \exp \left( - \frac{(t_r - s) \mathbb{E} [Y_{j}^{P_2}]}{\bar{w}} \right) \left( (1 + \eta) \ln(1 + \eta) - \eta \right) \right]
\]

\[
\leq \mathbb{E} \left[ \psi^* \left( \frac{\ln(1 + \varepsilon_{y,r})}{\bar{w}} \right) \exp \left( - \frac{t_r - s \varepsilon^2_{y,r} Z_r}{T} \right) \right)
\]

where the third inequality follows from $\psi^* (t) = \exp \left( t \left( (1 - \varepsilon_{y,r}) Z_r - \sum_{j=1+t_r}^{s+t_r} Y_{j}^{A_1} \right) \right)$; the fourth inequality from $Z_r \leq T \mathbb{E} [Y_{j}^{P_2}]$; the fifth inequality from $\sigma^2_{y,r} = \text{Var}(Y_{j}^{P_2}) \leq \bar{w} \mathbb{E} [Y_{j}^{P_2}]$.

With the inequalities (40)-(42), we can bound the failure probability of hybrid Algorithm $A_1^t P_2^{t_r-s}$ in stage $r$ by
According to Algorithm A in Algorithm 2, we allocate the $s$-th request to the channel $i^*$ which minimize the $F_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*})$. Thus we have

$$\mathcal{F}_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*}) \leq \mathcal{F}_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*})$$

Lemma G.4. $F_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*}) \leq F_r(A_1^{s-1} \overset{s^*}{\overline{P}}_T^{t^*})$

Proof. By the definition of $F_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*})$, we have that

$$F_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*}) = \mathbb{E} \left[ \phi_k^s \left( \frac{(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp \left( -\frac{t_r - s \varepsilon^2_{x,r}}{T} \right) + \varphi_k^s \left( \frac{(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp \left( -\frac{t_r - s \varepsilon^2_{x,r}}{T} \right) + \psi^s \left( \frac{(1 + \varepsilon_{y,r})}{\bar{w}} \right) \exp \left( -\frac{t_r - s \varepsilon^2_{y,r}}{T} \right) \right]$$

According to algorithm A in Algorithm 2, we allocate the $s$-th request to the channel $i^*$ which minimize the $F_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*})$. Thus we have

$$F_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*}) \leq \mathbb{E} \left[ \phi_k^s \left( \frac{(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp \left( -\frac{t_r - s \varepsilon^2_{x,r}}{T} \right) + \varphi_k^s \left( \frac{(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp \left( -\frac{t_r - s \varepsilon^2_{x,r}}{T} \right) + \psi^s \left( \frac{(1 + \varepsilon_{y,r})}{\bar{w}} \right) \exp \left( -\frac{t_r - s \varepsilon^2_{y,r}}{T} \right) \right]$$

Following the similar analysis in the inequality (40)-(42), we can show that

$$F_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*}) \leq \mathbb{E} \left[ \phi_k^s \left( \frac{(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp \left( -\frac{t_r - s + 1 \varepsilon^2_{x,r}}{T} \right) + \varphi_k^s \left( \frac{(1 + \varepsilon_{x,r})}{\bar{a}_k} \right) \exp \left( -\frac{t_r - s + 1 \varepsilon^2_{x,r}}{T} \right) + \psi^s \left( \frac{(1 + \varepsilon_{y,r})}{\bar{w}} \right) \exp \left( -\frac{t_r - s + 1 \varepsilon^2_{y,r}}{T} \right) \right]$$

which completes the proof.

In Lemma G.3, we have proven that $F_r(\overset{s^*}{\overline{P}}_T^{t^*}) \leq \delta$ and we will show that $F_r(A_1^s \overset{s^*}{\overline{P}}_T^{t^*}) \leq F_r(A_1^{s-1} \overset{s^*}{\overline{P}}_T^{t^*})$ in Lemma G.4.
Thus we have $\mathcal{F}_r(A_1^*) \leq \mathcal{F}_r(\hat{P}_2^*) \leq \delta$ by induction. Meanwhile, according to Theorem 4.2, we have that

$$
(1 - (4 + \frac{2}{\xi^* - \varepsilon})\varepsilon_{x,r-1})W_\varepsilon \leq Z_\varepsilon \leq W_\varepsilon
$$

with probability $1 - 2\delta$. During the stage $r$, the Algorithm $A_1$ return a solution satisfying

$$
\sum_{j=t_r+1}^{t_{r+1}} X_{jk}^{A_1} \leq \frac{(1 + \varepsilon_{x,r})t_r}{T} U_r, \forall k \in \mathcal{K}
$$

$$
\sum_{j=t_r+1}^{t_{r+1}} (\bar{a}_k - X_{jk}^{A_1}) \leq \frac{(1 + \varepsilon_{x,r})t_r}{T} ((1 - \varepsilon)T\bar{a}_k - L_k), \forall k \in \mathcal{K}
$$

$$
\sum_{j=t_r+1}^{t_{r+1}} Y_{j}^{A_1} \geq (1 - \varepsilon_{y,r})t_r \frac{Z_r}{T} \geq (1 - \varepsilon_{y,r})t_r (1 - (4 + \frac{2}{\xi^* - \varepsilon})\varepsilon_{x,r-1})W_\varepsilon
$$

with probability at least $1 - 3\delta$, since

$$
P \left( \left\{ \sum_{j=t_r+1}^{t_{r+1}} X_{jk}^{A_1} \leq \frac{(1 + \varepsilon_{x,r})t_r}{T}((1 + \varepsilon_{x,r})L_k - (\varepsilon(1 + \varepsilon_{x,r}) - \varepsilon_{x,r})T\bar{a}_k), \frac{(1 + \varepsilon_{x,r})t_r}{T}U_r, \forall k \in \mathcal{K} \right\} \cap \left\{ \sum_{j=t_r+1}^{t_{r+1}} Y_{j}^{A_1} \geq (1 - \varepsilon_{y,r})t_r \frac{Z_r}{T} \right\} \cap \left\{ Z_r \leq \frac{(1 + \varepsilon_{y,r} - \varepsilon_{x,r})t_r W_\varepsilon}{T} \left( 1 + \frac{1}{\xi^* - \varepsilon} \right) \right\} \right) \geq (1 - \delta)(1 - 2\delta) \geq 1 - 3\delta.
$$

Now considering all the stages, for the upper bound, we have

$$
\sum_{r=0}^{l-1} \sum_{j=t_r+1}^{t_{r+1}} X_{jk}^{A_1} \leq \sum_{r=0}^{l-1} \frac{(1 + \varepsilon_{x,r})t_r}{T} U_k \leq U_k.
$$

(44)

For the lower bound, we have

$$
(1 - \varepsilon)T\bar{a}_k - \sum_{r=0}^{l-1} \sum_{j=t_r+1}^{t_{r+1}} X_{jk}^{A_1} = \sum_{r=0}^{l-1} \sum_{j=t_r+1}^{t_{r+1}} (\bar{a}_k - X_{jk}^{A_1})
$$

$$
\leq \sum_{r=0}^{l-1} \frac{(1 + \varepsilon_{x,r})t_r}{T} ((1 - \varepsilon)T\bar{a}_k - L_k)
$$

$$
\leq (1 - \varepsilon)T\bar{a}_k - L_k.
$$

(45)

which is equivalent to

$$
\sum_{r=0}^{l-1} \sum_{j=t_r+1}^{t_{r+1}} X_{jk}^{A_1} \geq L_k.
$$

And for the revenue, we have

$$
\sum_{r=0}^{l-1} \sum_{j=t_r+1}^{t_{r+1}} Y_{j}^{A_1} \geq \sum_{r=0}^{l-1} (1 - \varepsilon_{y,r})t_r \frac{1}{T} (1 - (4 + \frac{2}{\xi^* - \varepsilon})\varepsilon_{x,r-1})W_\varepsilon
$$

$$
\geq \sum_{r=0}^{l-1} (1 - \varepsilon_{y,r})t_r \frac{1}{T} (1 - (4 + \frac{2}{\xi^* - \varepsilon})\varepsilon_{x,r-1})(1 - \frac{\varepsilon}{\xi})W_0
$$

(46)

$$
\geq (1 - O(\frac{\varepsilon}{\xi^* - \varepsilon}))W_0.
$$

since $\delta = \frac{\varepsilon}{3\xi}$, the inequalities (44)-(46) hold with probability at least $1 - \varepsilon$, which completes the proof of Theorem 4.5.
H. Proof of Theorem 5.2

Theorem 5.2. Under Assumption 1-3, if

\[ \gamma_2 = \max(\overline{a_k}, \bar{T_a} - L_k) = O\left(\frac{\epsilon^2}{\ln(K/\epsilon)}\right), \]

Algorithm \( t \), i.i.d. requests outputs \( \hat{\xi} \) such that

\[ \hat{\xi} \in [\xi^* - 4\epsilon_{x,r}, \xi^*] \]

w.p. \( 1 - 2\delta \), where \( \epsilon_{x,r} = \frac{q_4 \gamma_2 T \ln(K/\delta)}{t} \).

Proof. RHS: This side takes the same techniques as in Lemma G.1. First, the dual of LP (3) in Section 3.1 is

\[
\min_{\alpha, \beta, \rho} \sum_{k \in K} \alpha_k U_k - \sum_{k \in K} \beta_k L_k + \sum_{j \in J} T p_j \rho_j
\]

s.t.

\[
\sum_{k \in K} (\alpha_k - \beta_k) a_{ijk} + \rho_j \geq 0 \quad \forall i \in I, j \in J
\]

\[
\sum_{k \in K} T \bar{a}_k \beta_k = 1
\]

\[
\alpha_k, \beta_k, \rho_j \geq 0, \quad k \in K, j \in J.
\]

We denote the optimal solution of LP (3) in Section 3.1 and LP (47) as \((x^*_{ij}, \xi^*)\) and \((\alpha^*_k, \beta^*_k, \rho^*_k)\) respectively. According to the KKT conditions, we have that

\[
\sum_{k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x^*_{ij} + \rho^*_j x^*_{ij} = 0
\]

\[
\sum_{k \in K} T \bar{a}_k \beta_k^* = 1
\]

\[
\rho^*_j \left( \sum_{i \in I} x^*_{ij} - 1 \right) = 0
\]

\[
\alpha_k^* \left( \sum_{ij} T p_j a_{ijk} x^*_{ij} - U_k \right) = 0
\]

\[
\beta_k^* (L_k + \xi^* T \bar{a}_k - \sum_{ij} T p_j a_{ijk} x^*_{ij}) = 0
\]

Similarly, the dual of sampled LP (7) in Algorithm 5 is

\[
\min_{\alpha, \beta, \rho} \sum_{k \in K} \alpha_k t_r U_k - \sum_{k \in K} \beta_k t_r L_k + \sum_{j \in S_r} \rho_j
\]

s.t.

\[
\sum_{k \in K} (\alpha_k - \beta_k) a_{ijk} + \rho_j \geq 0 \quad \forall i \in I, j \in S_r
\]

\[
\sum_{k \in K} t_r \bar{a}_k \beta_k = 1
\]

\[
\alpha_k, \beta_k, \rho_j \geq 0, \quad k \in K, j \in S_r
\]

where \( S_r \) denotes the request set in stage \( r \). Since \((\alpha^*_k, \beta^*_k, \rho^*_k)\) is a feasible solution to the LP (47), the solution
\[ (\frac{T\alpha^*_k}{t_\gamma}, \frac{T\beta^*_k}{t_\gamma}, \frac{T\rho^*_k}{t_\gamma}) \text{ is feasible for the dual of sample LP } (49), \text{ we have that} \]

\[ \hat{\xi} + 2\epsilon_{x,r} = \frac{T}{t_r} \left( \sum_{k \in K} \alpha_k^* \frac{t_r}{T} U_k - \sum_{k \in K} \beta_k^* \frac{t_r}{T} L_k + \sum_{j \in S_r} \rho_j^* \right) \]

\[ = \frac{T}{t_r} \sum_{k \in K} \alpha_k^* \left( \frac{t_r}{T} U_k - \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* \right) + \frac{T}{t_r} \sum_{k \in K} \beta_k^* \left( \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* - \frac{t_r}{T} L_k \right) \]

\[ + \frac{T}{t_r} \sum_{j \in S_r} \left( \rho_j^* + \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* \right) \]

\[ = \frac{T}{t_r} \sum_{k \in K} \alpha_k^* \left( \frac{t_r}{T} U_k - \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* \right) + \frac{T}{t_r} \sum_{k \in K} \beta_k^* \left( \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* - \frac{t_r}{T} L_k \right) \]

where the final equality follows from the KKT conditions (48), i.e., \( \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* + \sum_{i \in I} \rho_j^* = \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* + \rho_j^* = 0 \) and \( \rho_j^*(\sum_{i \in I} x_{ij}^* - 1) = 0 \), so that \( \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* + \sum_{i \in I} \rho_j^* = \sum_{i \in I, k \in K} (\alpha_k^* - \beta_k^*) a_{ijk} x_{ij}^* + \rho_j^* = 0 \).

For those \( k \) such that \( L_k + \xi^* T\bar{a}_k < \sum_{i \in I, j \in J} T p_j a_{ijk} x_{ij}^* < U_k \), we know that they have no effect to \( \hat{\xi} \) following the complementary slackness in (48). For part (1), we only consider the resource \( k \) making \( \sum_{i \in I, j \in J} T p_j a_{ijk} x_{ij}^* = U_k \). By Lemma [B.1] it is easy to get that

\[ P( \sum_{j \in \{r, \ell\} \in I} a_{ijk} x_{ij}^* \leq (1 - \epsilon_{x,r}) \frac{t_r}{T} U_k ) \leq \exp \left( - \frac{t_r^2 \epsilon_{x,r}^2}{2(1 + \epsilon_{x,r}) \bar{a}_k \frac{U_k}{T}} \right) \]

(51)

where \( \mathbb{E}(\sum_{i \in I} a_{ijk} x_{ij}^*) = \frac{U_k}{T}, \forall j \in J \).

Similarly, for part (2), we only consider the constraints \( k \) making \( \sum_{i \in I, j \in J} T p_j a_{ijk} x_{ij}^* = L_k + \xi^* T\bar{a}_k \). Before that, we redefine the r.v. \( Y_{jk} = (1 + \xi^*) \bar{a}_k - \sum_{i \in I} a_{ijk} x_{ij}^* \). Since \( \xi^* \in [0, 1] \) from Assumption 3, we know that \( |Y_{jk}| \leq (1 + \xi^*) \bar{a}_k \) and \( E(Y_{jk}) = \frac{T\bar{a}_k - L_k}{T} \). Therefore, by Lemma [B.1]

\[ P( \sum_{j \in S_r} Y_{jk} \leq (1 - \epsilon_{x,r}) \frac{t_r}{T} (T\bar{a}_k - L_k) ) \leq \exp \left( - \frac{t_r^2 \epsilon_{x,r}^2}{2(1 + \epsilon_{x,r}) (1 + \xi^*) \bar{a}_k \frac{T\bar{a}_k - L_k}{T}} \right) \]

(52)

Since \( \gamma_2 = \max \left( \frac{\bar{a}_k}{t_\gamma}, \frac{\bar{a}_k}{t_\gamma - L_k} \right) = O\left( \frac{\epsilon_{x,r}^2}{\ln(\frac{1}{\delta})} \right) \), and both lower and upper bound are achieved only if \( U_k = T\bar{a}_k - L_k \), we have that

\[ \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* \geq (1 - \epsilon_{x,r}) \frac{t_r}{T} U_k \]

\[ \sum_{j \in S_r} ((1 + \xi^*) \bar{a}_k - \sum_{i \in I} a_{ijk} x_{ij}^*) \geq (1 - \epsilon_{x,r}) \frac{t_r}{T} (T\bar{a}_k - L_k) \]

w.p. at least \( 1 - \delta \).
Therefore, with probability at least $1 - \delta$ we have that

\begin{align*}
& (1) + (2) \\
& = \frac{T}{t_r} \left( \sum_{k \in \mathbb{K}} \alpha_k^* \left( \frac{t_r}{T} U_k - \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* \right) + \sum_{k \in \mathbb{K}} \beta_k^* \left( \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* - \frac{t_r}{T} L_k \right) \right) \\
& = \frac{T}{t_r} \left( \sum_{k \in \mathbb{K}} \alpha_k^* \left( \frac{t_r}{T} U_k - \sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* \right) + \sum_{k \in \mathbb{K}} \beta_k^* \left( \frac{t_r}{T} (T \bar{a}_k - L_k) - \sum_{j \in S_r} ((1 + \xi^*) \bar{a}_k - \sum_{i \in I} a_{ijk} x_{ij}^*) \right) \right) \\
& + \sum_{k \in \mathbb{K}} \beta_k^* \xi^* t_r \bar{a}_k \\
& \leq \frac{T}{t_r} \left( \epsilon_{x,r} \sum_{k \in \mathbb{K}} \alpha_k^* \frac{t_r}{T} U_k + \epsilon_{x,r} \sum_{k \in \mathbb{K}} \beta_k^* \frac{t_r}{T} (T \bar{a}_k - L_k) + \sum_{k \in \mathbb{K}} \beta_k^* \xi^* t_r \bar{a}_k \right) \\
& = \frac{T}{t_r} \left( \epsilon_{x,r} \left( \sum_{k \in \mathbb{K}} \alpha_k^* \frac{t_r}{T} U_k + \sum_{k \in \mathbb{K}} \beta_k^* \frac{t_r}{T} L_k \right) + \epsilon_{x,r} + \xi^* \right) \sum_{k \in \mathbb{K}} \beta_k^* t_r \bar{a}_k \\
& \leq \frac{T}{t_r} \left( \epsilon_{x,r} (\epsilon_{x,r}^{*} \epsilon_{x,r}^{*}) \frac{t_r}{T} + (\epsilon_{x,r} + \xi^*) \frac{t_r}{T} \right) \\
& = \xi^* (\epsilon_{x,r}^{*} + 1) \epsilon_{x,r} \\
& \leq \xi^* + 2 \epsilon_{x,r}
\end{align*}

where the first inequality from $\sum_{j \in S_r, i \in I} a_{ijk} x_{ij}^* \geq (1 - \epsilon_{x,r}) \frac{t_r}{T} U_k$ and $\sum_{j \in S_r, i \in I} (1 + \xi^*) \bar{a}_k - \sum_{i \in I} a_{ijk} x_{ij}^* \geq (1 - \epsilon_{x,r}) \frac{t_r}{T} (T \bar{a}_k - L_k)$; the second inequality from $\sum_{k \in \mathbb{K}} \beta_k^* T \bar{a}_k = 1$ and $\xi^* = \sum_{k \in \mathbb{K}} \alpha_k^* U_k - \sum_{k \in \mathbb{K}} \beta_k^* L_k + \sum_{j \in \mathbb{J}} T P_j \beta_j^* \geq \alpha_k^* U_k - \sum_{k \in \mathbb{K}} \beta_k^* L_k$; the last inequality follows from the fact $\xi^* \leq 1$.

**LHS:** We design an algorithm $\tilde{P}_3$ by allocating request $j$ to channel $i$ with probability $(1 - \epsilon_{x,r}) x_{ij}^*$, where $(x_{ij}^*, \xi^*)$ is the optimal solution for LP (7). Following the very similar proofs in Section 4.1 and letting $\gamma_2 = \max(\frac{a_k}{\bar{a}_k}, \frac{\bar{a}_k}{\bar{a}_k - L_k})$,

\[\epsilon_{x,r} = \sqrt{\frac{2 \gamma_2 T \ln(K/\delta)}{t_r}},\]

we have that

\[P \left( \sum_{j = 1}^{t_r} X_{j,k}^{\tilde{P}_3} \geq \frac{t_r}{T} U_k \right) \leq \exp \left( - \frac{t_r^2 \epsilon_{x,r}^{*} / T}{2(1 - \frac{2}{3} \epsilon_{x,r}) \frac{a_k}{\bar{a}_k}} \right) \leq \frac{\delta}{2K},\]

where the second inequality follows from the definition of $t_r$ and $\gamma_2 = O(\frac{T \ln(K/\delta)}{t_r})$, which result in $\epsilon_{x,r} < 1$. Defining $Y_{j,k}^{\tilde{P}_3} = (1 - \epsilon_{x,r})(1 + \xi^*) \bar{a}_k - X_{j,k}^{\tilde{P}_3}$, we have that $E(Y_{j,k}^{\tilde{P}_3}) \leq \frac{(1 - \epsilon_{x,r})(T \bar{a}_k - L_k)}{T}$ and $|Y_{j,k}| \leq (1 - \epsilon_{x,r})(1 + \xi^*) \bar{a}_k$, since $|X_{j,k}| \leq (1 - \epsilon_{x,r}) \bar{a}_k$. Therefore, we have

\[P \left( \sum_{j = 1}^{t_r} Y_{j,k}^{\tilde{P}_3} \geq \frac{t_r}{T} (T \bar{a}_k - L_k) \right) \leq \exp \left( - \frac{t_r^2 \epsilon_{x,r}^{*} / T}{2(1 - \frac{2}{3} \epsilon_{x,r}) (1 + \xi^*) \frac{a_k}{\bar{a}_k}} \right) \leq \frac{\delta}{2K},\]

Thus, with probability at least $1 - \delta$, we could find a solution whose consumed resource for each $k$ is in $\left[ \frac{t_r}{T} (L_k + (\xi^* - 2 \epsilon_{x,r}) T \bar{a}_k), \frac{t_r}{T} U_k \right]$ by Algorithm $\tilde{P}_3$. According to the definition of $\hat{\xi}$ in Algorithm 5, we have that $\hat{\xi} \geq \xi^* - 4 \epsilon_{x,r}$.

In conclusion, we have that $\xi^* - 4 \epsilon_{x,r} \leq \hat{\xi} \leq \xi^*$, w.p. $1 - 2\delta$.

Now $\hat{\xi}$ can be viewed as an good estimate for $\xi^*$ from 0, if we have enough data.
I. Proof of Theorem 5.3

Proof. We mainly consider two events, namely,

\[ G_1 = \left\{ \sum_{j=1}^{T} Y_j^{A_2} \geq (1 - O\left( \frac{\varepsilon}{\xi^* - 4\sqrt{\varepsilon} - \varepsilon} \right))W_0, \sum_{j=1}^{T} X_{jk}^{A_2} \in [L_k, U_k] \forall k \in K \right\}, \]

\[ G_2 = \left\{ \xi^* - 4\sqrt{\varepsilon} \leq \xi_0 \leq \xi^* \right\}. \]

Step 1.

When initializing Algorithm 6, we use the first \( \varepsilon T \) incoming requests to estimate the optimal measure of feasibility \( \xi^* \). From the Theorem 5.2, we have that \( P\{\{\xi^* - 4\sqrt{\varepsilon} \leq \xi_0 \leq \xi^*\}\} \geq 1 - 2\delta \), choosing \( \delta = \frac{\varepsilon}{3^{l+2}} \).

Step 2.

We investigate the conditional event \( G_1|G_2 \). Under the assumption \( \frac{\sqrt{\varepsilon}}{1-\sqrt{\varepsilon}} + 4\sqrt{\varepsilon} + \varepsilon \leq \xi^* \), if \( \xi^* - 4\sqrt{\varepsilon} \leq \hat{\xi}_0 \), we have \( \hat{\xi}_0 \geq \xi^* - 4\sqrt{\varepsilon} \geq \frac{\sqrt{\varepsilon}}{1-\sqrt{\varepsilon}} + \varepsilon \). Besides, we know that the domain

\[ L_k + \hat{\xi}_0 T \bar{a}_k \leq \sum_{i \in I, j \in J} T p_j a_{ijk} x_{ij} \leq U_k, \forall k \in K \]

\[ \sum_{i \in I} x_{ij} \leq 1, \forall j \in J \]

\[ x_{ij} \geq 0, \forall i \in I, j \in J, \]

is feasible under the assumption.

When \( \gamma_3 = O\left( \frac{\varepsilon^2}{m(K/\varepsilon)} \right) \), according to the Theorem 4.5, we have

\[ P\left( \sum_{j=1}^{T} Y_j^{A_2} \geq (1 - O\left( \frac{\varepsilon}{\hat{\xi}_0 - \varepsilon} \right))W_0 \right) \cap \left\{ \sum_{j=1}^{T} X_{jk}^{A_2} \in [L_k, U_k] \forall k \in K \right\} \geq 1 - 3l\delta, \]

where \( l = \log_2 \left( \frac{1}{\varepsilon} \right) \). Due to \( \hat{\xi}_0 \geq \xi^* - 4\sqrt{\varepsilon} \), we also could derive that \( P(G_1|G_2) \geq 1 - 3l\delta \).

Step 3.

Now we can verify that

\[ P(G_1^c) = P(G_1^c|G_2)P(G_2) + P(G_1^c|G_2^c)P(G_2^c) \]

\[ \leq P(G_1^c|G_2) + P(G_2^c) \]

\[ \leq 3l\delta + 2\delta = \varepsilon. \]

Therefore, \( P(G_1) \geq 1 - \varepsilon \), if \( \varepsilon \geq 0 \) and \( \tau_1 = \frac{\sqrt{\varepsilon}}{1-\sqrt{\varepsilon}} \) such that \( \tau_1 + 4\sqrt{\varepsilon} + \varepsilon \leq \xi^* \) and \( \gamma_3 = O\left( \frac{\varepsilon^2}{m(K/\varepsilon)} \right) \leq \max\left( \frac{\bar{a}_k}{U_k}, \frac{\bar{a}_k}{(1-\varepsilon)T \bar{a}_k - L_k}, \frac{W}{\varepsilon + \tau_1} \right). \)

\[ \square \]
