Abstract

We show both adaptive and non-adaptive minimax rates of convergence for a family of weighted Laplacian-Eigenmap based nonparametric regression methods, when the true regression function belongs to a Sobolev space and the sampling density is bounded from above and below. The adaptation methodology is based on extensions of Lepski’s method and is over both the smoothness parameter ($s \in \mathbb{N}_+$) and the norm parameter ($M > 0$) determining the constraints on the Sobolev space. Our results extend the non-adaptive result in Green et al. (2023), established for a specific normalized graph Laplacian, to a wide class of weighted Laplacian matrices used in practice, including the unnormalized Laplacian and random walk Laplacian.

1 INTRODUCTION

Consider the following regression model,

$$Y_i = f(X_i) + \varepsilon_i, \quad i = 1, \ldots, n, \quad (1)$$

where $f : \mathcal{X} \rightarrow \mathbb{R}$ is the true regression function, $X_i \overset{i.i.d.}{\sim} g$, where $g$ is a density on $\mathcal{X} \subset \mathbb{R}^d$, and $\varepsilon_i \overset{i.i.d.}{\sim} N(0, 1)$ is the noise (independent of the $X_i$’s). The goal is to estimate the regression function $f$ given pairs of observations $(X_1, Y_1), \ldots, (X_n, Y_n)$. Our main contribution in this work is to develop non-adaptive and adaptive estimators that achieve minimax optimal estimation rates, when $f$ lies in Sobolev spaces.

The estimators we study are based on performing principal components regression using the estimated eigenfunctions of a family of weighted Graph Laplacian operators. Various versions of Graph Laplacian matrices have been considered in the literature. Recently, Hoffmann et al. (2022) proposed a unifying framework describing a family of Graph Laplacian matrices, parametrized by $w \in \mathbb{R}^3$; see (2) and (3) for details. This captures Laplacian matrices used widely in practice, including the normalized, unnormalized and the random walk Laplacian.

Green et al. (2023) analyzed principal components regression specifically using unnormalized graph Laplacian matrices constructed over $\epsilon$-graphs, and established non-adaptive minimax rates when $f$ lies in Sobolev spaces. In this paper, we first extend this result to the entire family of weighted Laplacian matrices from (2) and (3); Theorem 3.1. These results are established by assuming a sampling density bounded from above and below and a true regression function belonging to a Sobolev space.

While the minimax rate optimal non-adaptive estimator depends on the knowledge of the smoothness and norm parameters of the true regression function, these parameters are unknown in practice. Tuning parameters, such as $\epsilon$, the graph radius (or the bandwidth for the kernel) and $K$, the number of eigenvectors considered, require knowledge of the smoothness and the norm parameters. Hence, in order to apply the Laplacian-based regression methodology in practice, we develop an adaptive estimator, based on Lepski’s method, and show in Theorem 3.2 that the developed estimator achieves minimax rates (up to log factors) without requiring the knowledge of either the smooth-
ness or the norm parameters.

The main technical contributions we make in this work towards establishing the aforementioned both adaptive and non-adaptive results include the following:

- As a part of the proofs of our main results in Theorem 3.1, we rigorously prove the idea roughly outlined by Hoffmann et al. (2022) on showing the convergence of the discrete weighted graph Laplacian matrices to their continuum counterparts (in appropriately well-defined sense) by leveraging the concentration result established by Giné and Guillou (2002) for kernel density estimators.

- We generalize the convergence property of the eigenvalues of the Laplacian matrices in Calder and Trillos (2022) to the weighted Laplacian matrices by providing an analogous bound for the eigenvalues combined with Weyl’s law.

- We formulate a simultaneous two-parameter Lepski’s procedure and obtain the adaptive minimax rate (see Theorem 3.2) through deriving a high-order-moment-based concentration inequality of the weighted Sobolev semi-norm.

Our contributions not only highlight the significance of utilizing the weighted graph Laplacians for nonparametric regression but also establish a solid statistical foundation for this method, offering a robust framework that underpins the reliability and effectiveness of this approach.

1.1 Related Works

Graph Laplacians are widely used in many data science problems for feature learning and spectral clustering (Weiss, 1999, Shi and Malik, 2000, Ng et al., 2001, von Luxburg, 2007), extracting heat kernel signatures for shape analysis (Sun et al., 2009, Andreux et al., 2015, Dunson et al., 2021), reinforcement learning (Mahadevan and Maggioni, 2007, Wu et al., 2019) and dimensionality reduction (Belkin and Niyogi, 2003, Coifman and Lafon, 2006), among other applications. There is an ever-growing literature on further applications of graph Laplacian in data science topics, and we also refer to Belkin et al. (2006), Wang et al. (2015), Chun et al. (2016) for more discussions.

As mentioned above, we consider the application of the weighted graph Laplacian for achieving minimax optimal rates in nonparametric regression. Other works focusing on this problem (including the semi-supervised setting) include Green et al. (2021) and Green et al. (2023) using unnormalized Laplacian based on the Laplacian eigenmaps (see Belkin and Niyogi, 2003), Bousquet et al. (2003) with Laplacian smoothing, Rice (1984) adopting spectral series regression on the Sobolev spaces, Trillos et al. (2022) applying the graph Poly-Laplacians (see Remark 3.4 for specific comparison to this method) and Hacquard et al. (2022) using topological data analysis. We also refer to Zhu et al. (2003), Zhou and Srebro (2011), Lee and Izbicki (2016), Dicker et al. (2017) and García Trillos and Murray (2020) for related analysis in the context of regression problems.

In recent years, there has been a great deal of progress on obtaining theoretical rates of convergence in the context of Laplacian operator estimation and related eigenvalue and/or eigenfunction estimation. Early work on consistency of graph Laplacians focused on pointwise consistency results for $\epsilon$-graphs, see Belkin and Niyogi (2005), Hein et al. (2005), Giné and Koltchinskii (2006), Hein et al. (2007) and references therein for more details. For fixed neighborhood size $\epsilon$, von Luxburg et al. (2008) and Rosasco et al. (2010) considered spectral convergence of graph Laplacians. Furthermore, Trillos and Slepčev (2018) established conditions on connectivity for the above spectral convergence with no specific error estimates. Later on, the convergence of Laplacian matrices to Laplacian operators has been considered, includes unnormalized, random walk Laplacians and $k$-NN graph based Laplacians in various work including Shi (2015), Calder and Trillos (2022). There, rates of convergences of Laplacian eigenvalues and eigenvectors to population counterparts with explicit error estimates are derived. Following the above literature, Hoffmann et al. (2022) developed a framework for extending the above convergence results to a general Laplacian family, the weighted Laplacians, and presented some heuristic asymptotic analysis.

To the best of our knowledge, the only work that considers adaptivity in the context of Laplacian estimation is Chazal et al. (2016). They use Lepski’s method for adaptive estimation of the unnormalized Laplace-Beltrami operators, focusing on bandwidth parameters. Also, they adopted a more flexible version of Lepski’s method introduced in Lacour and Massart (2016) that involves certain multiplicative coefficients introduced in the variance and bias terms to develop the method. Therefore, their proof technique is to consider the trade-off between the bounds on the approximation error and the variance of Laplacian estimators. However, in this paper, we apply Lepski’s method in the context of regression problem by using weighted Laplacians instead of just the unnormalized Laplacians (as in Chazal et al. (2016)). Additionally, besides the bandwidth parameter, our method is also adaptive to the smoothness parameter and the norm.
parameter of the Sobolev space under consideration, i.e., in our work, we use Lepski’s method for simultaneous adaptation to the unknown parameters of the function class under consideration.

2 PRELIMINARIES

In this section, we first describe the data-based weighted graph Laplacian matrices, and the corresponding nonparametric regression estimator. We then introduce the associated limiting operators and the weighted Sobolev spaces.

2.1 Weighted Graph Laplacian Matrices

Given i.i.d data $X_1, \ldots, X_n$ from a distribution $\mathcal{X} \subseteq \mathbb{R}^d$ with the density $g$, consider a graph $G$ with vertex set $\{X_1, \ldots, X_n\}$ and adjacency matrix $W$ given by

$$\tilde{w}_{i,j} := \frac{1}{n\eta} \eta \left( \frac{\|X_i - X_j\|}{\epsilon} \right), \quad i, j = 1, \ldots, n, \quad (2)$$

where $\|\cdot\|$ denotes the standard Euclidean norm. Here $\eta \geq 0$ is a kernel function with support $[0,1]$, and $\epsilon$ is the bandwidth parameter. In other words, $G$ is constructed by placing an edge $X_i \sim X_j$, when $\|X_i - X_j\| \leq \epsilon$, and this edge is given the weight $\tilde{w}_{i,j}$. The term ($n\eta^d$)$^{-1}$ is a convenient normalization factor. The degree matrix is then given by a diagonal matrix $\hat{D}$ with the $i$-th diagonal element as

$$\tilde{d}_i := \sum_{j=1}^{n} \tilde{w}_{i,j}, \quad i = 1, \ldots, n,$$

which can also be thought of as the kernel density estimator (KDE) of the density $g$ at $X_i$.

The weighted graph Laplacian matrices are a family of graph Laplacians consisting of various types of normalizations characterized by a parameter $w = (p, q, r) \in \mathbb{R}^3$ constructed as follows. First define a re-weighted adjacency matrix $W$ with $(i,j)$-th element as

$$w_{i,j}^c := \frac{\tilde{w}_{i,j}}{d_i^{1-p/2} d_j^{1-q/2}}, \quad i, j = 1, \ldots, n,$$

so that the corresponding diagonal degree matrix $D$ as entries

$$d_i := \sum_{j=1}^{n} w_{i,j}^c, \quad i = 1, \ldots, n.$$

Then, the weighted graph Laplacian after re-weighting is defined in Hoffmann et al. (2022) as follows: for a tuple $w = (p, q, r) \in \mathbb{R}^3$,

$$L_{w,n,c} := \begin{cases} \frac{1}{\epsilon^2} D^{-\frac{1}{2}} (D - W) D^{-\frac{1}{2}}, & \text{if } q \neq 1, \\ \frac{1}{\epsilon^2} (D - W), & \text{if } q = 1, \end{cases} \quad (3)$$

where $1/\epsilon^2$ is also a normalization factor. For $u \in \mathbb{R}^n$, the $i$-th coordinate of the vector $L_{w,n,c} u$ is given by

$$(L_{w,n,c} u)_i = \frac{1}{\epsilon^2} \sum_{j=1}^{n} d_i^{1-p/2} w_{i,j} \left( d_i^{-\frac{1}{2}} u_i - d_j^{-\frac{1}{2}} u_j \right), \quad (4)$$

The above weighted graph Laplacian (3) generalizes many commonly used graph Laplacian. For $(p, q, r) = (1,2,0)$, it recovers the unnormalized graph Laplacian $L_u$; if $(p, q, r) = (3/2, 2, 1/2)$, it gives the normalized graph Laplacian $L_n$; if $(p, q, r) = (2, 2, 0)$, it corresponds to a non-symmetric matrix but can be interpreted as a transition probability of a random walk on a graph denoted by $L_r$:

$$L_u := D - W, \quad L_n := D^{-1/2} (D - W) D^{1/2}, \quad L_r := D^{-1} (D - W),$$

While the main focus is on $\epsilon$-graphs, we highlight that the above formulation also captures the limits of graphs constructed based on the $k$-nearest neighbor graphs. In particular, when $(p, q, r) = (1, 1 - 2/d, 0)$, one can call the related normalization as the near $k$-NN normalization; see Calder and Trillos (2022) and Hoffmann et al. (2022) for details.

Note that the weighted Laplacian matrix $L_{w,n,c}$ is actually not self-adjoint with respect to the Euclidean inner product $\langle \cdot, \cdot \rangle$ since it is in general not symmetric. However, it is self-adjoint with respect to the following weighted inner product $\langle \cdot, \cdot \rangle_{g^{p-r}}$:

$$\langle \cdot, \cdot \rangle_{g^{p-r}} := \begin{cases} \langle \cdot, \cdot \rangle_D, & \text{if } q \neq 1, \\ \langle \cdot, \cdot \rangle, & \text{if } q = 1, \end{cases}$$

where for a given a symmetric matrix $A \in \mathbb{R}^{n \times n}$ and vectors $u, v \in \mathbb{R}^n$, define

$$\langle u, v \rangle_A := u^T A v.$$

We also define the normalized weighted inner product:

$$\langle \cdot, \cdot \rangle_{w,n} := n^{-1} \langle \cdot, \cdot \rangle_{g^{p-r}}$$

and the normalized Euclidean inner product: $\langle \cdot, \cdot \rangle_{n} := n^{-1} \langle \cdot, \cdot \rangle$ and denote by $\|\cdot\|_{w,n}$ and $\|\cdot\|_{n}$ their respective corresponding norms. Here, our estimation results are measured in $\|\cdot\|_{w,n}$ and under our assumptions in Section 3.1, it can be shown to be equivalent to the classic norm $\|\cdot\|_{n}$. 
2.2 Weighted Laplacian-Eigenmap Based Nonparametric Regression

Following the ideas in Belkin and Niyogi (2003) and Green et al. (2023), we propose the following principal components regression with the weighted Laplacian eigenmaps (PCR-WLE) algorithm:

1. For a given parameter $\epsilon > 0$ and a kernel function $\eta$, construct the $\epsilon$-graph according to Section 2.1.
2. Construct the weighted Laplacian matrix given by (3) and take its eigendecomposition $L_{w,n,\epsilon} = \sum_{i=1}^{n} \lambda_i v_i v_i^T$ with respect to $\langle \cdot, \cdot \rangle_{w,n}$, where $(\lambda_i, v_i)$ are the eigenpairs with eigenvalues $0 = \lambda_1 \leq \ldots \leq \lambda_n$ in an ascending order and eigenvectors normalized to satisfy $\|v_i\|_{w,n} = 1$.
3. Project the response vector $Y = (Y_1, \ldots, Y_n)^T$ onto the space spanned by the first $K$ eigenvectors, i.e., denote by $V_K \in \mathbb{R}^{n \times K}$ the matrix with $j$-th column as $V_{K,j} = v_j$ for $j = 1, \ldots, K$ and define $\hat{f} := V_K V_K^T Y$ as the estimator.

The entries of the vector $\hat{f}$ are the in-sample values of the estimator of the regression function $f$. Green et al. (2023) considered the special case of the above approach for the case when $(p,q,r) = (1,2,0)$ corresponding to the unnormalized graph Laplacian. Here, we consider the entire family of graph Laplacians for various choices of the parameters $(p,q,r)$, the generalization from Hoffmann et al. (2022).

2.3 Weighted Laplacians And Weighted Sobolev Spaces

Hoffmann et al. (2022) showed a heuristic framework for the convergence of the weighted graph Laplacian $L_{w,n,\epsilon}$ defined in (3) to the following weighted Laplace-Beltrami operators, in the large sample limit, in terms of the eigenvalues and eigenvectors/eigenfunctions:

$$
\begin{aligned}
L_u u := -\frac{1}{2g^{\prime\prime}} \text{div} \left( g^{\prime\prime} \nabla \left( \frac{u}{g^{\prime\prime}} \right) \right), & \quad \text{in } \mathcal{X}, \\
g^{\prime}\frac{\partial}{\partial n} \left( \frac{u}{g^{\prime\prime}} \right) = 0, & \quad \text{on } \partial \mathcal{X}.
\end{aligned}
$$

(5)

Special cases of this convergence, including convergences of $L_u, L_{n,\epsilon}$, have been studied in Calder and Trillos (2022), Trillos et al. (2020) as mentioned before in Section 1.1. Although our focus is not directly on the convergence of the weighted Laplacians but on the regression problems, the proof arguments in our paper can be applied to show the convergence of the weighted Laplacians by rigorously proving the heuristic idea in Hoffmann et al. (2022) via the concentration properties of kernel density estimation in Giné and Guillou (2002) when the domain is considered without boundary as it is well-known that the convergence of the Laplacian matrices to the Laplacian operators is problematic at the boundary (Belkin et al., 2012).

The weighted Laplacian operators are a generalization of the classical Laplacian operator with different values of $w = (p,q,r)$. Similar to the fact that the Laplacian operator is linked with the Sobolev space, the weighted Laplacian operators in (5) share a close connection with the following so-called weighted Sobolev spaces; see Triebel (1983) for a general introduction. Define the weighted $L^2$ space for $\ell > 0$ on $\mathcal{X}$ with a density $g$ as

$$
L^2(\mathcal{X}, g^\ell) := \left\{ u : \int_{\mathcal{X}} |u(x)|^2 g(x)^\ell dx < \infty \right\},
$$

with inner product

$$
\langle u, v \rangle_{g^\ell} := \int_{\mathcal{X}} u(x)v(x)g(x)^\ell dx.
$$

Then, for $w := (p,q,r) \in \mathbb{R}^3$ and $s \in \mathbb{N}_+$, we define the weighted Sobolev space as:

$$
H^s(\mathcal{X}, g) := \left\{ \frac{u}{g^s} \in L^2(\mathcal{X}, g^{p+q}) : \|u\|_{H^s(\mathcal{X}, g)} < \infty \right\},
$$

where the weighted Sobolev norm $\|u\|_{H^s(\mathcal{X}, g)}$ is

$$
\|u\|_{H^s(\mathcal{X}, g)}^2 := \sum_{j=1}^{s} |u|_{H^j(\mathcal{X}, g)}^2 + \left\| \frac{u}{g^s} \right\|_{L^2(\mathcal{X}, g^{p+q})}^2,
$$

with the $j$-th order semi-norm $|\cdot|_{H^j(\mathcal{X}, g)}$ defined as

$$
|u|_{H^j(\mathcal{X}, g)} := \sum_{|\alpha| = j} \|D^\alpha (ug^{-r})\|_{L^2(\mathcal{X}, g^{p+q})}
$$

and using multi-index notation with $x = (x^{(1)}, \ldots, x^{(d)}) \in \mathbb{R}^d$, $D^\alpha f(x) := \partial^{\alpha} f/\partial (x^{(1)})^{\alpha_1} \ldots \partial (x^{(d)})^{\alpha_d}$ and $|\alpha| = \alpha_1 + \ldots + \alpha_d$. When $g$ is uniform or $r = 0$ and $g$ is bounded from above and below, the weighted Sobolev space $H^s(\mathcal{X}, g)$ becomes (or is equivalent to) the classic Sobolev space $H^s(\mathcal{X})$. However, when $f/g^\ell$ is $s$-times differentiable but $f$ is not, the weighted Sobolev space differs from the classic Sobolev space. See Evans (2022) for more details regarding Sobolev spaces. For $M > 0$, the class of all functions $u$ such that $\|u\|_{H^s(\mathcal{X}, g)} \leq M$ is a weighted Sobolev ball $H^s(\mathcal{X}, g; M)$ of radius $M$.

Furthermore, we say a function $u \in H^s(\mathcal{X}, g)$ belongs to the zero-trace weighted Sobolev space $H^s_0(\mathcal{X}, g)$ if there exists a sequence $u_1 g^{-r}, \ldots, u_m g^{-r}$ of $C^\infty_c(\mathcal{X})$ functions such that

$$
\lim_{m \to \infty} \|u_m - u\|_{H^s(\mathcal{X}, g)} = 0,
$$

where $u_m$ is the $m$-th function in the sequence.
where $C_c^\infty(\mathcal{X})$ stands for the $C^\infty$ functions with compact support contained in $\mathcal{X}$.

Similar to the weighted Laplacian matrix $L_{w,n,\epsilon}$, the weighted Laplacian operators (5) are self-adjoint with respect to the following weighted inner product (Hoffmann et al. (2022)):

$$\langle u, v \rangle_{g^{p-r}} := \int_{\mathcal{X}} u(x)v(x)g^{p-r}(x)dx.$$ 

Note the following connection between the weighted norms and inner products:

$$\left\| \frac{u}{g^r} \right\|_{L^2(\mathcal{X}, g^{p-r})}^2 = \left\| u \right\|_{L^2(\mathcal{X}, g^{p-r})}^2 = \langle u, u \rangle_{g^{p-r}}.$$

A simple example showing the dependency of the choice $M$ on $p, q, r$ is as follows. Consider $u/g^r$ a constant function and is assumed to be 1 for simplicity and take $s = 1$. Then, we have

$$\left\| u \right\|_{H^1(\mathcal{X}, g)}^2 = \int_{\mathcal{X}} g(x)^{p+r}dx.$$

Clearly, the power $p+r$ of the density function $g$ determines the size of the weighted Sobolev ball, and thus $M$. In other words, say for example, assuming $q \geq 1$ for simplicity, larger configurations of $p + r$ will result in large weighted Sobolev norm, thus requiring a large norm parameter $M$. For generic $u/g^r$, the situation is more intricate and depends on the geometry of $u$ and $g$ and choices of $p + r$.

### 3 MAIN RESULTS

We now present our main results on adaptive and non-adaptive rates for estimating the regression function $f$ as in (1) under some smoothness assumptions. Before that, we recall that the minimax estimation error over $H^s(\mathcal{X}; M)$, a standard Sobolev ball of radius $M$, is given by

$$\inf_{f} \sup_{f_H \in H^s(\mathcal{X}; M)} \left\| \hat{f} - f \right\|_n^2 \asymp M^2(M^2n)^{-\frac{s}{2s+d}},$$

with high probability (Györfi et al., 2002, Wasserman, 2006, Tsybakov, 2008). Moreover, there are other methods that can achieve the above minimax rate such as kernel smoothing, local polynomial regression, thin-plate splines, etc. In this context, Green et al. (2023) showed that PCR-WLE method with the unnormalized Laplacian$^1$ $L_u$ achieves the minimax rate, provided that $n^{-1/2} \lesssim M \lesssim n^{s/d}$ under appropriate assumptions, where for two real-valued quantities, $A, B$, the notation $A \lesssim B$ means that there exists a constant $C > 0$ not depending on $f$, $M$ or $n$ such that $A \leq CB$ and $A \geq B$ stands for $A \leq B$ and $B \leq A$.

### 3.1 Assumptions

We now list the major assumptions that are needed for our theoretical results.

(A1) The distribution $G$ is supported on $\mathcal{X}$, which is an open, connected, and bounded subset of $\mathbb{R}^d$ with Lipschitz boundary.

(A2) The distribution $G$ has a density $g$ on $\mathcal{X}$ such that

$$0 < g_{\min} \leq g(x) \leq g_{\max} < \infty,$$

for all $x \in \mathcal{X}$, for some $g_{\min}, g_{\max} > 0$. Additionally, $g$ is Lipschitz on $\mathcal{X}$ with Lipschitz constant $L_g > 0$.

(A3) The kernel $\eta$ is a non-negative, monotonically non-decreasing function supported on the interval $[0, 1]$ and its restriction on $[0, 1]$ is Lipschitz and for convenience, we assume $\eta(1/2) > 0$ and define

$$\sigma_0 := \int_{\mathbb{R}} \eta(||x||)dx, \quad \sigma_1 := \frac{1}{d} \int_{\mathbb{R}^d} ||y||^2 \eta(||y||)dy.$$

Without loss of generality, we will assume $\sigma_0 = 1$ from now on.

(A4) The kernel $\eta$ satisfies a kernel VC-type condition as follows. Let

$$\mathcal{K} := \left\{ y \rightarrow \eta \left( \frac{x-y}{\epsilon} \right) : \epsilon > 0, x \in \mathbb{R} \right\}$$

be the collection of kernel functions indexed by $x$ and $\epsilon$. For a density $\rho$, let the $L^2(\mathcal{X}, \rho)$-covering number $N(\epsilon, \mathcal{K}, || \cdot ||_{L^2(\mathcal{X}, \rho)})$ of $\mathcal{K}$ be the smallest number of $L^2(\mathcal{X}, \rho)$-balls of radius $\epsilon$ needed to cover $\mathcal{K}$. With that we say that $\eta$ satisfies the kernel VC-type condition if there exist constants $A, \nu > 0$ such that

$$\sup_{\rho} N(\zeta, \mathcal{K}, || \cdot ||_{L^2(\mathcal{X}, \rho)}) \leq \left( \frac{A}{\zeta} \right)^\nu, \quad (6)$$

See Remark 3.2 for some examples.

Assumptions (A1) and (A2) are mild assumption on the density function, which are also made in Green et al. (2023). In particular (A2) is important for us, as it gives us the norm equivalence between the various families of weighted Sobolev spaces. Assumption (A3) is a standard normalization condition made on the smoothing kernel, also made in Green et al. (2023). Assumption (A4) is not used in Green et al. (2023). It is used here because the general family of weighted Laplacian matrices that we work with involve kernel density estimation normalization, with which the normalization in (3) will not tend to either infinity or

---

$^1$This procedure is referred to as PCR-LE in Green et al. (2023).
zero. Also note that in general condition (6) involves the $L^2(\mathcal{X}, \rho)$-norm of an envelope function $\eta_0$ for $\mathcal{K}$, i.e. of a function $\eta_0 \leq h$ for all $h \in \mathcal{K}$. Since, by our assumptions, $\eta$ is bounded, we can use the maximum of $\eta$ as an envelope, for which the $L^2(\mathcal{X}, \rho)$-norm obviously does not depend on $\rho$ and can thus be absorbed by the constant $A$.

### 3.2 Non-adaptive Rates

In the following, we present the non-adaptive minimax optimal rate of convergence of the PCR-WLE estimator in Section 2.2 for $s = 1$ and $s > 1$ separately. These rates are non-adaptive as the choice of $K$ and $\epsilon$ depends on unknown problem parameters, the smoothness parameter $s$ and the norm parameter $M$. In the following, we make a remark here that the norm $\| \cdot \|_{w,n}$ of an envelope function is generally evaluated at $X_1, \ldots, X_n$, i.e., we consider in-sample errors.

(a) For $s \in \mathbb{N}_+ \setminus \{1\}$, assume $f \in H^s_0(\mathcal{X},g;M)$, $f \in H^1(\mathcal{X},g;M)$ and $g \in C^{s-1}(\mathcal{X})$. Suppose there exist constants $c_0, C_0 > 0$ such that

$$c_0 \left( \frac{\log n}{n} \right)^{\frac{1}{2}} \vee (M^2n)^{-\frac{1}{2s-1}} \left( \mathcal{X} \right) \leq \epsilon \leq C_0 K^{-\frac{1}{2}},$$

and

$$\sqrt{\frac{\log \epsilon}{n}} \to 0,$$  \tag{7}

where

$$K = \min \left\{ \left( \frac{(M^2n)^{\frac{1}{2s-2}}}{} \right) \vee 1, n \right\}. \tag{8}$$

Then, there exist constants $c, C > 0$ not depending on $f, M$ or $n$ such that for $n$ large enough and any $0 < \delta < 1$, we have:

$$\| \hat{f} - f \|_{w,n}^2 \leq C \left\{ (\delta^{-1}M^2(M^2n)^{-\frac{s-2}{s-1}} \vee 1) \vee n^{-1} \right\},$$

with probability at least $1 - \delta - C_n e^{-\epsilon n^d} - e^{-K}$.  

(b) For $s = 1$, assume $f \in H^1(\mathcal{X},g;M)$. Suppose there exist constants $c_0, C_0 > 0$ such that

$$c_0 \left( \frac{\log n}{n} \right)^{\frac{1}{2}} \leq \epsilon \leq C_0 K^{-\frac{1}{2}},$$

and (7), where $K$ is given in (8) for $s = 1$. Then, the assertion in part (a) also holds for $s = 1$.

**Remark 3.1.** Notably, the above theorems do not require the assumption that $s > d/2$. As we mentioned before in Section 2.2, this condition is commonly appeared in the literature as in the sub-critical regime, i.e., $s \leq d/2$, the (weighted) Sobolev space $H^s$ is not a Reproducing Kernel Hilbert Space (RKHS) and cannot be continuously embedded into the space of continuous functions $C^0(\mathcal{X})$. Theorem 3.1 highlights the point that PCR-WLE algorithm obtains the minimax optimal rate when $n^{-1/2} \leq M \leq n^{d/4}$ and the error is measured by the weighted empirical norm $\| \cdot \|_{w,n}$.

**Remark 3.2.** The kernel VC-type condition was first proposed in Giné and Guillou (2002). A simple sufficient condition for this condition to hold is that $\eta$ is bounded variation; see Nolan and Pollard (1987) or Giné and Nickl (2021). Clearly, many common kernels are of this type, including Gaussian, Epanechnikov and cosine kernels. Furthermore, Matérn family of kernels is also of practical importance but is not considered a natural choice for kernels satisfying the required bounded variation condition due to the oscillatory behavior of the Bessel function while the bounded variation condition is generally associated with functions that do not oscillate too wildly. However, some special cases of the family indeed satisfy the bounded variation condition. For smoothness parameters $\nu = p + 1/2$ of Matérn kernels with positive integer $p$, the Matérn kernels can be expressed as a product of an exponential and a polynomial whose derivative is absolutely integrable, and thus they satisfy the condition. Moreover, the Matérn kernel becomes the Gaussian (RBF) kernel in the limit of $\nu \to \infty$, thereby satisfying the VC-type condition.

**Remark 3.3.** For practical consideration, there are two tuning parameters: the graph radius (the bandwidth for the kernel $\eta$) $\epsilon$ and the number of eigenvalues $K$. The lower bound for $\epsilon$ makes sure that with this smallest radius, the resulting weighted graph will still be connected with high probability and the upper bound for $\epsilon$ ensures the eigenvalue of the weighted graph Laplacian (3) to be of the same order as its continuum version, the eigenvalue of the weighted Laplacian operator (5) (Weyl’s law). The asymptotic assumption on $\epsilon$ is from the concentration of the KDE. The condition on $K$ is set to trade-off bias and variance. Both $\epsilon$ and $K$ depend on the true smoothness parameter $s \in \mathbb{N}_+$.

### 3.3 Adaptive Rates Via Lepski’s Method

Despite the minimax optimality of the PCR-WLE algorithm shown in Section 3.2, the main practical difficulties are the choice of several tuning parameters including the bandwidth parameter (or the graph radius) $\epsilon$ and the number of eigenvalues $K$, because optimal choices depend on the unknown true smoothness parameter $s$ of the regression function $f$ in the model. Moreover, $K$ also relies on the bound of the weighted Sobolev norm $M$. This naturally brings
about the issue of adaptation, which we address using Lepski’s method. Note that, as we are concerned with in-sample estimation error, other techniques like cross-validation are not directly applicable to set the tuning parameters.

Since its introduction in Lepski (1991), Lepski’s method has been widely used for adaptive estimation and testing in various statistical contexts; e.g., see Birgé (2001), Chichignoud et al. (2016), Bellec et al. (2021), Lacour and Massart (2016). In the following, we consider Lepski’s method on the product space of the smoothness parameter \( s \in \mathbb{N}_+ \) and the constraint on the weighted Sobolev norm \( M \in \mathbb{R}_+ \).

Recall that \( s \) and \( M \) denote the true smoothness parameter and the norm parameter, respectively for the weighted Sobolev norm of \( f \). Here, we actually take \( M \) as the minimum over all bounds of the weighted Sobolev norm. We start by picking \( s_{\min}, s_{\max} \in \mathbb{N}_+ \); here we can set \( s_{\min} = 1 \) under no availability of further information\(^2\) regarding the knowledge of \( s \). The goal is that \( s_{\max} \) is large enough that \( s \in [s_{\min}, s_{\max}] \). Similarly, we pick \( M_{\min}, M_{\max} \) satisfying \( 0 < M_{\min} < M_{\max} < \infty \), where \( M_{\min} \) and \( M_{\max} \) are small and large enough respectively such that \( M \in [M_{\min}, M_{\max}] \). Next, define the grid \( B \times D \) as \( \{(s_j, M_j)\}_{j=1}^{N_1} \) given by:

\[
B := [s_{\min}, s_{\max}] \cap \mathbb{N}_+ = \{s_{\min} =: s_1 < s_2 < \ldots < s_{N_1} := s_{\max}\},
\]

and

\[
D := [M_{\min}, M_{\max}] = \{M_{\min} =: M_1 < M_2 < \ldots < M_{N_1} := M_{\max}\},
\]

where \( N_1 \asymp \log n \).

For any pair \((\hat{s}, \hat{M})\) in the above grid, let \( \hat{f}_{\hat{s},\hat{M}} \) be the PCR-WLE estimator in Section 2.2 corresponding to the parameters \( \hat{s} \) and \( \hat{M} \). We define the Lepski’s estimator as

\[
\hat{f}_{\text{adapt}} := \hat{f}_{\hat{s},\hat{M}},
\]

where \( \hat{s} \) is given by

\[
\hat{s} := \max \{s \in B : \|\hat{f}_{s,M} - \hat{f}_{s',\hat{M}}\|_{w,n} \leq c_0 \hat{M}'(\hat{M}'^2 n / \log n)^{-\frac{1}{2s' + d}} \text{, } \forall s', \hat{s}' \in B\},
\]

and \( \hat{M}' \) is the corresponding couple of \( s \) in the grid, where \( c_0 > 0 \) is some finite constant. Here, we formulate the above simultaneous Lepski’s method by coupling the smoothness parameter and the norm parameter and only maximize through the smoothness parameter instead of dealing with a joint maximization, which is not needed for our purpose of showing the adaptive minimax rate in the following result as our focus is its convergence rate in \( n \).

The following result presents a near minimax optimal rate of convergence of the Lepski’s estimator \( \hat{f}_{\text{adapt}} \) up to a logarithmic factor in \( n \).

**Theorem 3.2.** Assume (A1)-(A4) and \( g \in C^{s-1}(\mathcal{X}) \). Also, assume \( f \in H^1(\mathcal{X}, g; M) \cap H^1(\mathcal{X}, g; M) \) and \( \hat{f}_g := f/g \) is \( M \)-Lipschitz, i.e., \( \|\hat{f}_g(x) - \hat{f}_g(x')\| \leq M\|x - x'\| \) for any \( x, x' \in \mathcal{X} \). Furthermore, assume that (for large enough \( n \)) we have \( s \in [s_{\min}, s_{\max}] \) and \( M \in [M_{\min}, M_{\max}] \). Then, under the minimax optimal setting in Theorem 3.1 for \( M \), i.e., \( n^{-1/2} \lesssim M \lesssim n^{s/d} \), the estimator \( \hat{f}_{\text{adapt}} \) satisfies: For \( n \) large enough and any \( \delta \in (0, 1) \), there exists some constant \( C > 0 \) such that

\[
\|\hat{f}_{\text{adapt}} - f\|^2_{w,n} \leq C\delta^{-1}M^2(M^2 n / \log n)^{-\frac{2}{2s + d}},
\]

with probability at least

\[
1 - \delta \log^{-2s/(2s + d)} n - C n^{-C n^{-d}} \log^2 n - 16 C c_0^{-4} n^{-1} \log^{2 - 2s_{\min}}(2s_{\min} + d) n - e^{-[M_{\min}^2]^d/(2s + d)} \log^2 n.
\]

**Remark 3.4.** Trillos et al. (2022) proposed a graph poly-Laplacian regularization approach, where integer powers of the Laplacian matrices are used as regularization in a least-squares context. They showed that the proposed method achieves rate of convergence of order \( n^{-s/(d + 4s)} \). While the rate is not optimal, in comparison to the Green et al. (2023) their estimator does not require the knowledge of the norm parameter \( M \) to achieve the derived rate (although they require the knowledge of \( s \)). In comparison to both the above works, our result in Theorem 3.2 achieves the optimal rate, up to log factors, without requiring the knowledge of either \( s \) or \( M \).

**Remark 3.5.** As a part of our proof, a better concentration inequality for the non-adaptive PCR-WLE estimator \( \hat{f} \) is required compared to Theorem 3.1, for which the assumption that \( \hat{f}_g \) is Lipschitz is required. As also discussed in Green et al. (2023, see below Theorem 1), it remains open whether a weaker assumption or even the weighted Sobolev condition \( \|\nabla \hat{f}_g\|_{L^2} < \infty \) alone might be sufficient to establish the required concentration result for developing adaptive procedures.
4 CONCLUSION

In this work, we provide adaptive and non-adaptive rates of convergence, in Theorem 3.1 and 3.2 respectively, for estimating a true regression function lying belonging to the Sobolev space. Our estimators are based on performing principal components regression based on the eigenvectors of the weighted graph Laplacian matrix, and using Lepski’s method for deriving the adaptive results. Our contributions expand upon the non-adaptive outcome outlined in Green et al. (2023), which was originally established for a particular normalized graph Laplacian. This extension encompasses a broad spectrum of weighted Laplacian matrices commonly employed in practical applications, including the unnormalized Laplacian and the random walk Laplacian among them.

Future works include (i) relaxing the assumption that the density $g$ is bounded from below, (ii) developing confidence intervals for the estimators by establishing asymptotic normality results and developing related bootstrap procedures, and (iii) developing estimators that are instance-optimal in the sense of Hoffman and Lepski (2002), i.e., estimators that achieve the best possible rate for a given combination of the true regression function $f$ and the sampling density $g$ by adaptively picking the parameters $p$, $q$ and $r$ in the weighted graph Laplacian matrix.

Checklist

1. For all models and algorithms presented, check if you include:
   (a) A clear description of the mathematical setting, assumptions, algorithm, and/or model. [Yes]
   (b) An analysis of the properties and complexity (time, space, sample size) of any algorithm. [Yes]
   (c) (Optional) Anonymized source code, with specification of all dependencies, including external libraries. [Not Applicable]

2. For any theoretical claim, check if you include:
   (a) Statements of the full set of assumptions of all theoretical results. [Yes]
   (b) Complete proofs of all theoretical results. [Yes]
   (c) Clear explanations of any assumptions. [Yes]

3. For all figures and tables that present empirical results, check if you include:
   (a) The code, data, and instructions needed to reproduce the main experimental results (either in the supplemental material or as a URL). [Not Applicable]
   (b) All the training details (e.g., data splits, hyperparameters, how they were chosen). [Not Applicable]
   (c) A clear definition of the specific measure or statistics and error bars (e.g., with respect to the random seed after running experiments multiple times). [Not Applicable]
   (d) A description of the computing infrastructure used. (e.g., type of GPUs, internal cluster, or cloud provider). [Not Applicable]

4. If you are using existing assets (e.g., code, data, models) or curating/releasing new assets, check if you include:
   (a) Citations of the creator If your work uses existing assets. [Not Applicable]
(b) The license information of the assets, if applicable. [Not Applicable]
(c) New assets either in the supplemental material or as a URL, if applicable. [Not Applicable]
(d) Information about consent from data providers/curators. [Not Applicable]
(e) Discussion of sensible content if applicable, e.g., personally identifiable information or offensive content. [Not Applicable]

5. If you used crowdsourcing or conducted research with human subjects, check if you include:
   (a) The full text of instructions given to participants and screenshots. [Not Applicable]
   (b) Descriptions of potential participant risks, with links to Institutional Review Board (IRB) approvals if applicable. [Not Applicable]
   (c) The estimated hourly wage paid to participants and the total amount spent on participant compensation. [Not Applicable]
Adaptive and non-adaptive minimax rates for weighted Laplacian-Eigenmap based nonparametric regression: Supplementary Materials

5 PROOF

5.1 Proof Of Theorem 3.1

In this section, we will prove both Theorem 3.1 for $s = 1$ and $s > 1$ together. We first present and prove some auxiliary lemmas. We will denote by $B_x(r)$ a closed Euclidean ball with midpoint $x$ and radius $r \geq 0$.

Define the weighted Sobolev seminorm $\langle L_{w, t} f, f \rangle_{g^{p-r}}$ given by the following non-local operator:

$$L_{w, t} f(x) := \frac{1}{c^{d+2}} \int_{\mathcal{X}} \frac{\eta\left(\frac{\|x-y\|}{\epsilon}\right)}{g(x)^{1-q/2}g(y)^{1-q/2}} \left( g(x)^{-r} f(x) - g(z)^{-r} f(z) \right) g(z) dz,$$

where according to (4), $L_{w, t}$ can be viewed as a population counterpart of the discrete graph weighted Laplacian $L_{w, n}$.

As in Green et al. (2023), we also call it a ‘non-local’ version. Note that the above non-local weighted Sobolev seminorm and non-local operator generalize the definitions in Green et al. (2023) as the latter belong to a special case when $(p, q, r) = (1, 2, 0)$. The following Lemmas 5.1-5.6 therefore extend their counterparts in Green et al. (2023) to the weighted Laplacians and the weighted Sobolev seminorm. Note that in our proofs, we also highlight and fix several important typos and errors that appeared in Green et al. (2023). Despite the errors, the final results in Green et al. (2023) remain true.

Lemma 5.1. For $f \in H^1(\mathcal{X}; g; M)$, we have

$$\langle L_{w, t} f, f \rangle_{g^{p-r}} \lesssim M^2.$$  

Proof of Lemma 5.1. Following the idea of Green et al. (2021, Proof of Lemma 1), take $\Omega$ as an arbitrary bounded open set such that $B_x(c_0) \subseteq \Omega$ for all $x \in \mathcal{X}$ for some $c_0 > 0$ and we can assume that $f \in H^1(\Omega, g)$ and $\|f\|_{H^1(\Omega, g)} \lesssim \|f\|_{H^1(\mathcal{X}; g)}$ without loss of generality due to the existence of an extension operator $E : H^1(\mathcal{X}, g) \rightarrow H^1(\Omega, g)$ such that $Ef$ satisfies these properties, see Theorem 1 in Chapter 5.4 in Evans (2022). Also, since $C^\infty(\Omega)$ is dense in $H^1(\Omega, g)$ and the integral in Lemma 5.1 is continuous in $H^1(\Omega, g)$, we can assume $f_g := f/g^r \in C^\infty(\Omega)$ so that

$$f_g(x') - f_g(x) = \int_0^1 \nabla f_g(x + t(x' - x))' (x' - x) dt.$$

Then, we have by symmetry in the first step:

$$2 \langle L_{w, t} f, f \rangle_{g^{p-r}}$$

$$= \frac{1}{c^{d+2}} \int_{\mathcal{X}} \int_{\mathcal{X}} \frac{\eta\left(\frac{\|x-y\|}{\epsilon}\right)}{g(x)^{1-q/2}g(y)^{1-q/2}} \left| \frac{f(x)}{g(x)^r} - \frac{f(y)}{g(y)^r} \right|^2 g(x)g(y) dx dy$$

$$= \frac{1}{c^{d+2}} \int_{\mathcal{X}} \int_{\mathcal{X}} \frac{\eta\left(\frac{\|x-y\|}{\epsilon}\right)}{g(x)^{1-q/2}g(y)^{1-q/2}} \left( \int_0^1 \nabla f_g(y + t(x - y))' (x - y) dt \right)^2 g(x)g(y) dx dy$$

$$\leq \frac{1}{c^{d+2}} \int_{\mathcal{X}} \int_{\mathcal{X}} \int_0^1 \frac{\eta\left(\frac{\|x-y\|}{\epsilon}\right)}{g(x)^{1-q/2}g(y)^{1-q/2}} \left( \nabla f_g(y + t(x - y))' (x - y) \right)^2 g(x)g(y) dx dy$$

$$\leq \int_{\mathcal{X}} \int_{B_0(1)} \int_0^1 (\nabla f_g(y + \epsilon t z)' z)^2 \frac{\eta(\|z\|)}{g(y + \epsilon z)^{1-q/2}g(y)^{1-q/2}} g(y + \epsilon z)g(y) dtdz dy,$$

with $(x - y)/\epsilon = z$

$$\lesssim \int_{\mathcal{X}} \int_{B_0(1)} \int_0^1 (\nabla f_g(y + \epsilon t z)' z)^2 \eta(\|z\|)g(y + \epsilon t z)^q dtdz dy.$$
\[ \leq \int_{B_0(1)} \int_0^1 (\nabla f_{\hat{y}}(\hat{y}^T z)^2 \eta(z) g(\hat{y})^q dtd\hat{y}, \ \hat{y} = y + ct \in \Omega. \] (10)

Since we have \((\nabla f_{\hat{y}}(\hat{y}^T z)^2 = \left( \sum_{i=1}^d (\nabla f_{\hat{y}}(\hat{y}))^{(i)} z^{(i)} \right)^2\) \(\text{and } \eta(z)\) is invariant with respect to the rotation, it yields that

\[ \int_{B_0(1)} (\nabla f_{\hat{y}}(\hat{y}^T z)^2 \eta(z) dz = \sum_{i,j=1}^d (\nabla f_{\hat{y}}(\hat{y}))^{(i)}(\nabla f_{\hat{y}}(\hat{y}))^{(j)} \int_{B_0(1)} z^{(i)} z^{(j)} \eta(z) dz \]
\[ = \sum_{i=1}^d \left( (\nabla f_{\hat{y}}(\hat{y}))^{(i)} \right)^2 \int_{B_0(1)} (z^{(i)})^2 \eta(z) dz \]
\[ = \sigma_1 \| \nabla \left( f(\hat{y}) / g(\hat{y})^r \right) \|^2. \] (11)

Plugging (11) in (10), we conclude

\[ 2\langle L_{w,e}f, f \rangle_{g^{p-r}} \lesssim \sigma_1 M^2. \]

This finishes the proof. \(\square\)

Note that the proof of Lemma 5.1 also utilized the heuristic arguments given in Hoffmann et al. (2022) while we provide a rigorous proof here.

**Lemma 5.2.** Suppose \(f \in L^2(\mathcal{U}, g^{p+r}; M)\) for a Borel set \(\mathcal{U} \subseteq \mathcal{X}\). Then, there exists a constant \(C\) which does not depend on \(f\) or \(M\) such that

\[ \|L_{w,e}f\|_{L^2(\mathcal{U}, g^{p+r})} \leq C \epsilon^2 \|f\|_{L^2(\mathcal{U}, g^{p+r})}. \]

**Proof.** By Cauchy-Schwarz inequality, we have

\[ |L_{w,e}f(x)|^2 = \frac{1}{\epsilon^{2(d+2)}} \left( \int_{\mathcal{U}} g(x)^{1-p} \eta\left( \frac{\|x-z\|}{\epsilon} \right) \left( g(x)^{-r} f(x) - g(z)^{-r} f(z) \right) g(z) dz \right)^2 \]
\[ \lesssim \frac{1}{\epsilon^{2(d+2)} g(x)^{2(1-p)}} \int_{\mathcal{U}} \eta\left( \frac{\|x-z\|}{\epsilon} \right) \left( f(x) - f(z) \right)^2 dz \cdot \int_{\mathcal{X}} g(x)^{1/q^2} g(z)^{1/q^2} dz \]
\[ \lesssim \frac{2\sigma_0}{\epsilon^{4+d}} g(x)^{2(q-p)} \int_{\mathcal{U}} \eta\left( \frac{\|x-z\|}{\epsilon} \right) \left( |f(x)|^2 + |f(z)|^2 \right) dz. \]

Then, we have

\[ \|L_{w,e}f\|_{L^2(\mathcal{U}, g^{p+r})}^2 = \int_{\mathcal{U}} g^{p-r}(x) |L_{w,e}f(x)|^2 dx \]
\[ \lesssim \frac{2}{\epsilon^{4+d}} \int_{\mathcal{U}} \int_{\mathcal{U}} g(x)^{2(q-p)+p-r}(x) \eta\left( \frac{\|x-z\|}{\epsilon} \right) \left( |f(x)|^2 + |f(z)|^2 \right) dz dx \]
\[ \lesssim \frac{2}{\epsilon^{4+d}} \int_{\mathcal{U}} \int_{\mathcal{U}} \eta\left( \frac{\|x-z\|}{\epsilon} \right) \left( |f(x)|^2 + |f(z)|^2 \right) dz dx \]
\[ \lesssim \frac{4}{\epsilon^{4+d}} \int_{\mathcal{U}} \int_{\mathcal{U}} \eta\left( \frac{\|x-z\|}{\epsilon} \right) |f(x)|^2 dz dx \]
\[ \lesssim \frac{4}{\epsilon^4} \int_{\mathcal{U}} |g(x)^{p+r}(x) f(x)|^2 dx \]
\[ \lesssim \frac{4}{\epsilon^4} \|f\|_{L^2(\mathcal{U}, g^{p+r})} \]

\(\square\)
Lemma 5.3. Suppose $f_g \in L^2(U, g^{p+\gamma}; M)$ for a Borel set $U \subseteq \mathcal{X}$. Then, there exists a constant $C > 0$ such that

$$E_{w,e}(f; U) \leq \frac{C}{\epsilon^2} \|f_g\|^2_{L^2(U, g^{p+\gamma})},$$

where we define the Dirichlet energy for the set $U$ as

$$E_{w,e}(f, U) := \frac{1}{\epsilon^{d+2}} \int_U \int_U (g(x)^{-\gamma} f(x) - g(z)^{-\gamma} f(z))^2 \frac{\eta \left( \frac{\|x-z\|}{\epsilon} \right)}{g(x)^{1-q/2} g(z)^{1-q/2}} g(x)g(z) dx dz.$$

Proof. Note that

$$E_{w,e}(f; U) = \frac{1}{\epsilon^{d+2}} \int_U \int_U (g(x)^{-\gamma} f(x) - g(z)^{-\gamma} f(z))^2 \frac{\eta \left( \frac{\|x-z\|}{\epsilon} \right)}{g(x)^{1-q/2} g(z)^{1-q/2}} g(x)g(z) dx dz$$

$$\quad \leq \frac{2}{\epsilon^{d+2}} \int_U \int_U (|g(x)^{-\gamma} f(x)|^2 + |g(z)^{-\gamma} f(z)|^2) \frac{\eta \left( \frac{\|x-z\|}{\epsilon} \right)}{g(x)^{1-q/2} g(z)^{1-q/2}} g(x)g(z) dx dz$$

$$\quad = \frac{4}{\epsilon^{d+2}} \int_U \int_U |g(x)^{-\gamma} f(x)|^2 \eta \left( \frac{\|x-z\|}{\epsilon} \right) g(x)^{q/2} g(z)^{q/2} dx dz$$

$$\quad \approx \frac{4}{\epsilon^{d+2}} \int_U \int_U |g(x)^{-\gamma} f(x)|^2 \eta \left( \frac{\|x-z\|}{\epsilon} \right) g(x)^{p+\gamma} dx dz$$

$$\quad \approx \frac{4}{\epsilon^{d+2}} \int_U |g(x)^{-\gamma} f(x)|^2 g(x)^{p+\gamma} dx.$$ \hfill \Box

We denote by $\mathcal{X}_e$ a subset of $\mathcal{X}$ such that for any $x \in \mathcal{X}_e$, $B_x(t\epsilon) \in \mathcal{X}$ consisting of points sufficiently far away from the boundary and $\partial_x \mathcal{X}$ by its complement within $\mathcal{X}$ consisting of points close enough to the boundary.

Lemma 5.4. For $f \in H^1(\mathcal{X}, g; M) \cap H^2(\mathcal{X}, g; M)$ with $s \in \mathbb{N}_+$ and $g \in C^{s-1}(\mathcal{X})$, there exist constants $C_1, C_2 > 0$ such that

(1) If $s$ is odd, then we have with $t = (s-1)/2$:

$$\|L^t_{w,e} f - \sigma_1^t L^t_{w} f\|_{L^2(\mathcal{X}_e, g^{p+\gamma})} \leq C_1 M \epsilon.$$

(2) If $s$ is even, then we have with $t = (s-2)/2$:

$$\|L^t_{w,e} f - \sigma_1^t L^t_{w} f\|_{L^2(\mathcal{X}_e, g^{p+\gamma})} \leq C_2 M \epsilon^2.$$

Proof. Without loss of generality, we assume both $g$ and $f$ are $C^\infty(\mathcal{X})$ due to the fact that $C^\infty(\mathcal{X})$ is dense in both $H^s(\mathcal{X}, g)$ and $C^{s-1}(\mathcal{X})$ and the norm in the statements is continuous with respect to $\| \cdot \|_{H^s(\mathcal{X}, g)}$ and $\| \cdot \|_{C^{s-1}(\mathcal{X})}$.

Actually, we claim the following stronger result: for $t < s/2$ and every $x \in \mathcal{X}_e$,

$$L^t_{w,e} f(x) = \sigma_1^t L^t_{w} f(x) + \sum_{j=1}^{\lfloor (s-1)/2 \rfloor - t} r_{2(j+t)}(x) \epsilon^{2j} + r_s(x) \epsilon^{s-2t}, \quad (12)$$

for some functions $r_j$ such that

$$\|r_j\|_{H^{s-j}(\mathcal{X}_e, g)} \leq C \|g\|_{C^{s-1}(\mathcal{X})} M. \quad (13)$$

Note that the dependence of the functions $r_j$ on $t$ is suppressed in the notation.
The key idea underlying the proof of (12) is to consider the following Taylor expansion. For an $s$-times differentiable function $F : \mathcal{X} \to \mathbb{R}$ and $x \in \mathcal{X}$, define the following operator $d^s_x$:

$$(d^s_x F)(z) := \sum_{|a|=s} D^a F(x) z^a.$$ 

Also, define $d^s F := \sum_{|a|=s} D^a F$. Then, for $\phi \in C^s(\mathcal{X})$ and some $h > 0$, $z \in \mathcal{X}_h$, $x \in B_z(h)$, the Taylor expansion at $z$ is given as:

$$\phi(x) = \phi(z) + \sum_{j=1}^{s-1} \frac{1}{j!} (d^j_x \phi)(x - z) + R_s(x, z; \phi).$$

Here, we note that $(d^j_x \phi)(z)$ is a polynomial of degree $j$ and we have for any $y \in \mathbb{R}$:

$$(d^j_x \phi)(yz) = y^j (d^j_x \phi)(z).$$

The remainder term $R_j(x, z; \phi)$ is

$$R_j(x, z; \phi) := \frac{1}{(j-1)!} \int_0^1 (1 - \theta)^{j-1} (d^j_{x+\theta(x-z)} \phi)(x - z) d\theta,$$

such that for any $x^* \in B_0(1)$,

$$\sup_{x \in \mathcal{X}_h} |R_j(x, x + hx^*; \phi)| \leq C h^j \|\phi\|_{C^j(\mathcal{X})},$$

and

$$\int_{\mathcal{X}_h} |R_j(z + \theta h x, z; \phi)|^2 dz \leq h^{2j+2} \int_{\mathcal{X}_h} \int_0^1 |(d^j_{x+\theta h x} \phi)(z)|^2 d\theta dz \leq h^{2j} \|d^j \phi\|_{L^2(\mathcal{X})}^2.$$ 

Now, we apply the above Taylor expansion on the function $f_g(x) := f(x)/g(x)^r$ up to order $s$ and the function $g^{q/2}(x)$ up to order $S$ in $L_{w, \epsilon} f(x)$, where $S = 1$ if $s = 1$ and otherwise $S = s - 1$ and obtain:

$$L_{w, \epsilon} f(x) = \frac{1}{\epsilon^{d+s+2}} \sum_{j_1=1}^{s-1} \sum_{j_2=0}^{S-1} \frac{1}{j_1! j_2!} \int_{\mathcal{X}} g(x)^{q/2-p} \left( \frac{\|x - z\|}{\epsilon} \right) (d^{j_1}_{x} f_g)(x - z)(d^{j_2}_{x} g^{q/2})(z - x) dz$$

$$+ \frac{1}{\epsilon^{d+s+2}} \sum_{j=1}^{s-1} \frac{1}{j!} \int_{\mathcal{X}} g(x)^{q/2-p} \left( \frac{\|x - z\|}{\epsilon} \right) (d^{j}_{x} f_g)(x - z) R_S(x, z; g^{q/2}) dz$$

$$+ \frac{1}{\epsilon^{d+2}} \int_{\mathcal{X}} g(x)^{p/2-p} \left( \frac{\|x - z\|}{\epsilon} \right) R_s(x, z; f_g) g(z)^{q/2} dz.$$ 

Now, with the transformation $y = (z - x)/\epsilon$, we have

$$L_{w, \epsilon} f(x) = -\frac{1}{\epsilon^2} \sum_{j=1}^{s-1} \sum_{j_2=0}^{S-1} \frac{\epsilon^{j_1+j_2}}{j_1! j_2!} \int_{B_0(1)} g(x)^{q/2-p} \left( \|y\| \right) (d^{j_1}_{x} f_g)(y)(d^{j_2}_{x} g^{q/2})(y) dy$$

$$- \frac{1}{\epsilon^2} \sum_{j=1}^{s-1} \frac{\epsilon^{j}}{j!} \int_{B_0(1)} g(x)^{q/2-p} \left( \|y\| \right) (d^{j}_{x} f_g)(y) R_S(x, ey + x; g^{q/2}) dy$$

$$+ \frac{1}{\epsilon^2} \int_{B_0(1)} g(x)^{p/2-p} \left( \|y\| \right) R_s(x, ey + x; f_g) g(ey + x)^{q/2} dy$$

$$=: L_1(x) + L_2(x) + L_3(x).$$

We will now prove (12) by induction on $t$, and throughout this proof, with a slight abuse of notation, the functions $r_j$ in (12) may vary from line to line depending on $t$ at the induction step but they will always satisfy the condition (13) as we are only interested in the bounds.
Firstly, we start with $L_1(x)$. If $s = 1$, we can see $L_1(x) = 0$. Therefore, in the following, we only focus on $s \geq 2$. Now, we define

$$l_{j_1, j_2}(x) := \int_{B_0(1)} g(x)^{q/2-p} \eta(||y||)(d_x^{j_1} f_g)(y)(d_x^{j_2} g^{q/2})(y)dy,$$

such that

$$L_1(x) = -\frac{1}{e^2} \sum_{j_1+j_2 \geq 0} \sum_{j_1 \geq 1} \sum_{j_2 \geq 1} \epsilon_{j_1+j_2} l_{j_1, j_2}(x).$$

Since $(d_x^{j_1} f_g)(y)$ is a polynomial of degree $j$, $l_{j_1, j_2}$ actually depends on the sum $j_1 + j_2$ and $d_x^{j_1} d_x^{j_2}$ is an order $j_1 + j_2$ multivariate monomial. Therefore, when $j_1 + j_2$ is odd, we have

$$l_{j_1, j_2}(x) = 0.$$

Then, when $s = 2$, we have $j_1 + j_2 = 1$ and $L_1(x) = 0$. As for $s \geq 3$, we notice that the lowest order term of $L_{11}(x)$ is from $j_1 + j_2 = 2$, which means either $j_1 = 1, j_2 = 1$ or $j_1 = 2, j_2 = 0$. We have

$$l_{1,1}(x) = \int_{B_0(1)} g(x)^{q/2-p} \eta(||y||)(d_x^{1} f_g)(y)(d_x^{1} g^{q/2})(y)dy$$

$$= \sum_{i_1=1, i_2=1}^{d} \sum_{i_1=1, i_2=1}^{d} g(x)^{q/2-p}(D f_g(x))^{(i_1)}(D g^{q/2}(x))^{(i_2)} \int_{B_0(1)} ||y||^2 \eta(||y||)dy,$$

and

$$\frac{1}{2} l_{2,0}(x) = \int_{B_0(1)} g(x)^{q/2-p} \eta(||y||)(d_x^{2} f_g)(y)(d_x^{2} g^{q/2})(y)dy$$

$$= \frac{1}{2} \sum_{i_1=1}^{d} g(x)^{q/2-p}((D f_g(x))^{(i_1)})^{2} g(x)^{q/2} \int_{B_0(1)} ||y||^2 \eta(||y||)dy.$$ 

Therefore, we have by definition:

$$\mathcal{L}_w f(x) = -\frac{1}{2g(x)^p} \left( \nabla g(x)^q \cdot \nabla \left( \frac{f(x)}{g(x)^r} \right) + g(x)^q \Delta \left( \frac{f(x)}{g(x)^r} \right) \right),$$

and

$$-(l_{1,1}(x) + \frac{1}{2} l_{2,0}(x)) = \sigma_1 \mathcal{L}_w f(x).$$

This is exactly the leading term. We remark here that in Green et al. (2023, Section D.2), the negative sign is missing, which does not actually give the Laplacian operator by the leading term. Now, it remains to bound the higher order terms with $j_1 + j_2 > 2$. We will show that

$$L_1(x) = \sigma_1 \mathcal{L}_w + \sum_{j=1}^{[(s-1)/2]-1} r_{2(j+1)}(x) \epsilon^{2j} + r_s(x) \epsilon^{s-2}.$$ 

It suffices to show for $j_1 + j_2 > 2$, $l_{j_1, j_2}$ satisfies (13) for $j = \min\{j_1 + j_2 - 2, s - 2\}$. Through the multi-index notation, we write that

$$l_{j_1, j_2}(x) = g(x)^{q/2-p} \sum_{|\alpha_1| = j_1, |\alpha_2| = j_2} D^{|\alpha_1|} f_g(x) D^{|\alpha_2|} g^{q/2}(x) \int_{B_0(1)} y^{\alpha_1} y^{\alpha_2} \eta(||y||)dy,$$

where $|\int_{B_0(1)} y^{\alpha_1} y^{\alpha_2} \eta(||y||)dy| < \infty$ for all $\alpha_1, \alpha_2$. Then, by Hölder’s inequality, we have for $|\alpha_1| = j_1, |\alpha_2| = j_2$,

$$\|g(x)^{q/2-p} D^{|\alpha_1|} f_g D^{|\alpha_2|} g^{q/2} \|_{H^{-j_1,j_2}(X,g)} \lesssim \|D^{|\alpha_1|} f_g\|_{H^{-j_1,j_2}(X,g)} \|g(x)^{q/2-p} D^{|\alpha_2|} g^{q/2} \|_{C^{-j_1,j_2}(X)}.$$
Summing over all $|\alpha_1| = j_1$ and $|\alpha_2| = j_2$, we obtain that $I_{j_1,j_2}$ satisfies (13).

Next, as for $L_2(x)$, note that if $s = 1$, $L_2(x) = 0$. We want to show that for $s \geq 2$,

$$\|L_2\|_{L^p(X, g^{s+r})} \leq C \varepsilon^{-2} M \|g\|_{C^{s-1}(X)}.$$

Clearly, if $s = 1$, $L_2(x) = 0$. Now, for $s \geq 2$, we have $S = s-1$ and since $|R_{s-1}(x, x + \varepsilon x^*)| \leq C \varepsilon^{-1} \|g\|_{C^{s-1}(X)}$

for any $x^* \in B_0(1)$ and $d^2(\cdot)$ is a $j$-homogeneous function, we have

$$|L_2(x)| \leq \sum_{j=1}^{s-1} \frac{c^j}{j!} \int_{B_0(1)} g(x)^{q/2-p} \eta(||y||) \cdot |R_S(x, \varepsilon y + x; g^{q/2})| dy$$

$$\leq C \varepsilon^{-2} \|g\|_{C^{s-1}(X)} \sum_{j=1}^{s-1} \frac{1}{j!} \int_{B_0(1)} g(x)^{q/2-p} \eta(||y||) \cdot \sqrt{(d^2 x^j f_g)(y)} dy.$$

Moreover, we have by Cauchy–Schwarz inequality,

$$\int_{X_1} g(x)^{p+r} \left( \int_{B_0(1)} g(x)^{q/2-p} \eta(||y||) \sqrt{(d^2 x^j f_g)(y)} dy \right)^2 dx$$

$$\leq \int_{X_1} g(x)^{q-p+r} \left( \int_{B_0(1)} \eta(||y||) \sqrt{(d^2 x^j f_g)(y)^2} dy \right)^2 dx$$

$$\leq \sigma_0 \int_{B_0(1)} \int_{X_1} g(x)^{q-p+r} \eta(||y||) \sqrt{(d^2 f_g)(x)^2} dx dy$$

$$\leq \sigma_0^2 \int_{X_1} g(x)^{p+r} \sqrt{(d^2 f_g)(x)^2} dx$$

$$= \sigma_0^2 \|d^2 f_g\|_{L^2(X, g^{s+r})}^2,$$

where in the last step, we use the fact that $|d^2 x^j f(y)| \leq |d^j f(x)|$ for all $y \in B_0(1)$. Therefore, it yields that

$$\int_{X_1} g(x)^{p+r} |L_2(x)|^2 dx$$

$$\leq C \varepsilon^{-2} \|g\|_{C^{s-1}(X)} \int_{X_1} g(x)^{p+r} \left( \frac{1}{j!} \int_{B_0(1)} g(x)^{q/2-p} \eta(||y||) \sqrt{(d^2 x^j f_g)(y)} dy \right)^2 dx$$

$$\leq C \varepsilon^{-2} \|g\|_{C^{s-1}(X)} \int_{X_1} \|d^2 f_g\|_{L^2(X, g^{s+r})}^2.$$
Finally, according to (14), we have
\[ L_{w,c}^{t+1} f(x) = (L_{w,c} \circ L_{w,c}^t f)(x) \]
\[ = \sigma_1 L_{w,c} L_{w,c}^t f(x) + \sum_{j=1}^{(s-1)/2} L_{w,c} r_{2(j+t)}(x) \epsilon^{2j} + L_{w,c} r_s(x) \epsilon^{s-2t}. \quad (15) \]

In the following, we will bound these terms on the right-hand side individually. First of all, since \( L_{w,c}^t f \in H^{s-2t}(X, g; C \|g\|_{L^2(\partial \mathcal{X}, \delta)}) \), applying (14) yields
\[ L_{w,c} L_{w,c}^t f(x) = \sigma_1 L_{w,c} L_{w,c}^t f(x) + \sum_{j=1}^{(s-2t-1)/2} r_{2j+2, s-2t}(x) \epsilon^{2j} + r_{s-2t, s-2t}(x) \epsilon^{s-2t-2} \]
\[ = \sigma_1 L_{w,c} L_{w,c}^t f(x) + \sum_{j=1}^{(s-1)/2} r_{2(t+j)}(x) \epsilon^{2j} + r_s(x) \epsilon^{s-2(t+1)}, \quad (16) \]
where we apply the fact mentioned before that \( r_{j,t}(x) = r_{(s-t)+j}(x) \).

Next, suppose \( j < [(s-1)/2] - t \). We apply (14) and obtain
\[ L_{w,c} r_{2(j+t)}(x) = \sigma_1 L_{w,c} r_{2(j+t)}(x) + \sum_{i=1}^{(s-2j-2t-1)/2} r_{2i+2, s-2(j+t)}(x) \epsilon^{2i} \]
\[ + r_{s-2(j+t), s-2(j+t)}(x) \epsilon^{s-2(j+t)-2} \]
\[ = r_{2(j+t+1)}(x) + \sum_{i=1}^{(s-1)/2} r_{2(i+j+t+1)}(x) \epsilon^{2i} + r_s(x) \epsilon^{s-2(j+t+1)}, \]
where we use the fact that \( r_{j,t}(x) = r_{(s-t)+j}(x) \) and \( \sigma_1 L_{w,c} r_{2(j+t)}(x) = r_{2,s-2(j+t)}(x) = r_{2(j+t+1)}(x) \). Therefore, we have
\[ L_{w,c} r_{2(j+t)}(x) \epsilon^{2j} = r_{2(j+t+1)}(x) \epsilon^{2j} + \sum_{m=1}^{(s-1)/2} r_{2(m+t+1)}(x) \epsilon^{2m} + r_s(x) \epsilon^{s-2(k+1)}, \quad (17) \]
where the last equality is by changing the variable \( m = i + j \). Moreover, when \( j = [(s-1)/2] - t \), we have \( 2(j+t) = 2[(s-1)/2] \) and we simply calculate that
\[ L_{w,c} r_{2(j+t)}(x) \epsilon^{2j} = r_{s-2(j+t)}(x) \epsilon^{s-2(j+k)} \epsilon^{2j} = r_s(x) \epsilon^{s-2(k+1)}. \quad (18) \]
Finally, according to (14), we have
\[ L_{w,c} r_s(x) \epsilon^{s-2t} = r_s(x) \epsilon^{s-2(t+1)}. \quad (19) \]
Combining (16)-(19) with (15), we obtain the proof for \( t + 1 \). \( \square \)

Recall that we write \( \mathcal{X} = \mathcal{X}_{te} \cup \partial \mathcal{X}_{te} \), where for any \( x \in \mathcal{X}_{te} \), \( B_x(te) \subset \mathcal{X} \) and \( \partial \mathcal{X}_{te} \) as its complement within \( \mathcal{X} \) consisting of points close to the boundary.

**Lemma 5.5.** For \( f \in H^s(X, g; M) \) and \( t > 0 \) such that \( 2t < s \), there exists a constant \( c > 0 \) not depending on \( M \) or \( f \) such that for all \( \epsilon < c \),
\[ \| L_{w,c}^t f \|^2_{L^2(\partial \mathcal{X}_{te}, \mathcal{X}_{te}, g^{p+r})} \lesssim c^{2(s-2t)} M^2. \]

**Proof.** Note that according to Lemma 5.2, we have
\[ \| L_{w,c}^t f \|^2_{L^2(\partial \mathcal{X}_{te}, \mathcal{X}_{te}, g^{p+r})} \lesssim \frac{1}{\epsilon^2} \| L_{w,c}^{t-1} f \|^2_{L^2(\partial \mathcal{X}_{te}, \mathcal{X}_{te}, g^{p+r})} \lesssim \cdots \lesssim \frac{1}{\epsilon^{2t}} \| f \|^2_{L^2(\partial \mathcal{X}_{te}, \mathcal{X}_{te}, g^{p+r})}. \]
Therefore, it suffices to show for all $\epsilon < c$,
\[
\|f_g\|_{L^2(\partial_e, \mathcal{X}, g^{p+r})}^2 \lesssim \epsilon^{2s} \|f\|_{H^s(\mathcal{X}, g)}^2.
\]  
(20)

In order to deal with $f_g$ near the boundary, we will take a similar procedure used in Green et al. (2023, Proof of Lemma 5) and Leoni (2017, Theorem 18.1) as follows. With loss of generality, we take $t = 1$ as one can view $\epsilon < c/t$ for proving for the general case.

**Step 1: Local patch.** We assume that for some $c_0 > 0$ and a Lipschitz mapping $\phi : \mathbb{R}^{d-1} \rightarrow [-c_0, c_0]$ and since $f \in H^s_0(\mathcal{X}, g; M)$, without loss of generality, we can assume that $f_g \in C_\infty^s(U_\psi(c_0))$ with

\[
U_\psi(c_0) := \{ y \in Q(0, c_0) : \psi(y^{(-d)}) \leq y^{(d)} \},
\]
where $Q(0, c_0)$ is the $d$-dimensional hypercube of side length $c_0$ centered at 0. Now, following step 1 in Green et al. (2023, Proof of Lemma 5) by replacing $f$ as $f_g$, we have

\[
|f_g(y)|^2 \lesssim \epsilon^{2s-1} \left( \int_{\psi(y^{(-d)})}^{\psi(y^{(d)})} |(D^s f_g(y^{(-d)}, z))^{(d)}| dz \right)^2
\]
\[
\lesssim \epsilon^{2s-1} \int_{\psi(y^{(-d)})}^{\psi(y^{(d)})} |(D^s f_g(y^{(-d)}, z))^{(d)}|^2 dz.
\]

Then, we obtain:

\[
\int_{V_\psi(\epsilon)} g(y)^{p+r} |f_g(y)|^2 dy \lesssim \int_{Q_{d-1}(c_0)} \psi(y^{(-d)})^{+\epsilon} |f_g(y^{(-d)}, y^{(d)})|^2 dy dy^{(-d)}
\]
\[
\lesssim \epsilon^{2s-1} \int_{Q_{d-1}(c_0)} \psi(y^{(-d)})^{+\epsilon} \int_{Q_{d-1}(c_0)} \psi(y^{(-d)})^{+\epsilon} |(D^s f_g(y^{(-d)}, z))^{(d)}|^2 dz dy^{(-d)} dy^{(d)},
\]
(21)

where $Q_{d-1}(0, c_0)$ is the $d$-dimensional hypercube of side length $c_0$ centered at 0. Also, by changing the integration order, it yields that

\[
\int_{\psi(y^{(-d)})}^{\psi(y^{(d)})} |(D^s f_g(y^{(-d)}, z))^{(d)}|^2 dz dy^{(-d)} \lesssim \epsilon \int_{\psi(y^{(-d)})}^{\psi(y^{(d)})} |(D^s f_g(y^{(-d)}, z))^{(d)}|^2 dz
\]
\[
\lesssim \epsilon \int_{\psi(y^{(-d)})}^{\psi(y^{(d)})} |(D^s f_g(y^{(-d)}, z))^{(d)}|^2 dz.
\]
(22)

Combining (21) and (22), we obtain:

\[
\int_{V_\psi(\epsilon)} g(y)^{p+r} |f_g(y)|^2 dy \lesssim \epsilon^{2s} \int_{Q_{d-1}(c_0)} \psi(y^{(-d)})^{+\epsilon} g(y^{(-d)}, z) \| (D^s f_g(y^{(-d)}, z))^{(d)} \|^2 dz dy^{(-d)}
\]
\[
\lesssim \epsilon^{2s} \|f\|^2_{H^s(U_\psi(c_0), g)}.
\]

**Step 2: Rigid motion of local patch.** Now suppose at a point $x_0 \in \partial \mathcal{X}$, there exit a rigid motion $T : \mathbb{R}^d \rightarrow \mathbb{R}^d$ such that $T(x_0) = 0$, and a number $C_0$ such that we have all $C_0 \epsilon \leq c_0$.

\[
T(Q_T(x_0, c_0) \cap \partial \mathcal{X}) \subseteq V_\psi(C_0 \epsilon) \quad \text{and} \quad T(Q_T(x_0, c_0) \cap \mathcal{X}) = U_\psi(c_0),
\]
(23)

where $Q_T(x_0, c_0)$ is a hypercube in $\mathbb{R}^d$ of side length $c_0$ centered at $x_0$ (not necessarily coordinate-axis-aligned). Let $v_g(y) := f_g(T^{-1}(y))$ and $v(y) := f(T^{-1}(y))$ for all $y \in U_\psi(c_0)$. Then, if $f_g \in C_\infty^s(\mathcal{X})$, we have $v_g \in C_\infty^s(U_\psi(c_0))$ such that $\|v_g\|^2_{H^s(U_\psi(c_0))} = \|f_g\|^2_{H^s(U_\psi(c_0)) \cap \mathcal{X}}$. Therefore, according to Step 1, we have

\[
\int_{V_\psi(C_0 \epsilon)} g(x)^{p+r} |v_g(y)|^2 dy \lesssim \epsilon^{2s} \|v_g\|^2_{H^s(U_\psi(c_0)), g}.
\]
Then, it yields that
\[
\int_{Q_T(x_0, c_0) \cap \partial \mathcal{X}} g^{p+r}(x)|f_g(x)|^2 \, dx \\
= \int_{T(Q_T(x_0, c_0) \cap \partial \mathcal{X})} g^{p+r}(y)|v_g(y)|^2 \, dx \\
\lesssim \int_{V_{\psi}(c_0 \epsilon)} g(x)^{p+r}|v_g(y)|^2 \, dy \\
\lesssim \epsilon^{2s} \|v\|_{H^r(U_{\psi}(c_0), g)}^2 \\
\lesssim \epsilon^{2s} \|f\|^2_{H^s(X, g)}.
\]

**Step 3: Lipschitz domain.** Now we arrive at the last step where we shall deal with the case: \( \mathcal{X} \) is assumed to be an open, bounded subset of \( \mathbb{R}^d \) with Lipschitz boundary. Again, following the procedure in Green et al. (2023, Proof of Lemma 5). In this case, for every \( x_0 \in \partial \mathcal{X} \), there exists a rigid motion \( T_{x_0} : \mathbb{R}^d \to \mathbb{R}^d \) such that \( T_{x_0}(x_0) = 0 \), a number \( c_0(x_0) \), a Lipschitz mapping \( \psi : \mathbb{R}^d \to [-c_0(x_0), c_0(x_0)] \) and a number \( C_0(x_0) \) satisfying for all \( C_0(x_0) \epsilon \leq c_0(x_0) \), (23) holds for replacing \( c_0, C_0, T, \psi \) by \( c_0(x_0), C_0(x_0), T_{x_0}, \psi_{x_0} \) respectively. Therefore, by Step 2, we have
\[
\int_{Q_{T_{x_0}}(x_0, c_0(x_0)) \cap \partial \mathcal{X}} g^{p+r}(x)|f_g(x)|^2 \, dx \lesssim_{x_0} \epsilon^{2s} \|f\|^2_{H^s(X, g)}.
\]
Although the constant in the last bound depends on \( x_0 \), by compactness assumption, there exists a finite subset (denoted by \( x_{0,1}, \ldots, x_{0,N} \)) of the collection of hypercubes \( \{Q_{T_{x_0}}(x_0, c_0(x_0))/2 : x_0 \in \partial \mathcal{X} \} \) which covers \( \partial \mathcal{X} \). Then, by taking the minimum of all constants with respect to \( x_{0,1}, \ldots, x_{0,N} \), we can conclude that
\[
\partial_r(\mathcal{X}) \subseteq \bigcup_{i=1}^N Q_{T_{x_{0,i}}}(x_{0,i}, c_0(x_{0,i})).
\]
Consequently, we have
\[
\int_{\partial \mathcal{X}} g^{p+r}(x)|f_g(x)|^2 \, dx \lesssim \sum_{i=1}^N \int_{Q_{T_{x_{0,i}}}(x_{0,i}, c_0(x_{0,i})) \cap \partial \mathcal{X}} g^{p+r}(x)|f_g(x)|^2 \, dx \lesssim \epsilon^{2s} \|f\|^2_{H^s(X, g)}.
\]
Therefore, we proved the desired result (20).

The following result presents a higher order version of Lemma 5.1 for \( s > 1 \) and the non-local weighted Sobolev seminorm, \( \langle L_{w,e}^s, f, f \rangle_{g^{p-r}} \).

**Lemma 5.6.** For \( f \in H^1(\mathcal{X}, g; M) \cap H^0_0(\mathcal{X}, g; M) \) with \( s \in \mathbb{N}_+ \setminus \{1\} \), we have
\[
\langle L_{w,e}^s, f, f \rangle_{g^{p-r}} \lesssim M^2.
\]

**Proof of Lemma 5.6.** Note here that we fix the assumption that \( f \in H^1(\mathcal{X}, g; M) \) besides \( f \in H^0_0(\mathcal{X}, g; M) \), which is missing in the statement of Green et al. (2023, Theorem 3). In general, it is not true for \( \mathcal{X} \neq \mathbb{R}^d \) that \( H^1(\mathcal{X}, g; M) = H^1(\mathcal{X}, g; M) \). Based on Lemma 5.1, we will prove Lemma 5.6 in a recursive way for \( s > 1 \). Recall that \( L_{w,e} \) is self-adjoint with respect to the weighted inner product, meaning \( \langle L_{w,e} f_1, f_2 \rangle_{g^{p-r}} = \langle f_1, L_{w,e} f_2 \rangle_{g^{p-r}} \) for any \( f_1/g^r, f_2/g^r \in L^2(X, g^{p+r}) \). Also recall the definition of the Dirichlet energy given in Lemma 5.3, which can be stated as \( E_{w,e}(X, \mathcal{X}) = 2 \langle L_{w,e}^1, f, f \rangle_{g^{p-r}} \).

Following the procedure in Green et al. (2023) \(^3\), when \( s = 2t + 1 \) for \( t \geq 1 \), by using self-adjointness, we have
\[
\langle L_{w,e}^s, f, f \rangle_{g^{p-r}} = \langle L_{w,e}^{t+1} f, L_{w,e}^{t} f \rangle_{g^{p-r}} = \frac{1}{2} E_{w,e}(L_{w,e}^1, \mathcal{X}).
\]

\(^3\)We remark here that the factor 2 is missing in (Green et al., 2023, Section D.4).
We divide the Dirichlet energy into two parts:
\[ E_{w,e}(L^t_{w,e} f, \mathcal{X}) = \frac{1}{c^d+2} \int_{\mathcal{X}_{te}} \int_{\mathcal{X}_{te}} (g(x)^{-r} f(x) - g(z)^{-r} f(z))^2 \frac{\eta \left( \frac{\|x-z\|}{\epsilon} \right)}{g(x)^{1-q/2} g(z)^{1-q/2}} g(x) g(z) dx dz \]
\[ + \frac{1}{c^d+2} \int_{\partial_{te} \mathcal{X}} \int_{\partial_{te} \mathcal{X}} (g(x)^{-r} f(x) - g(z)^{-r} f(z))^2 \frac{\eta \left( \frac{\|x-z\|}{\epsilon} \right)}{g(x)^{1-q/2} g(z)^{1-q/2}} g(x) g(z) dx dz \]
\[ =: E_{w,e}(L^t_{w,e} f, \mathcal{X}_{te}) + E_{w,e}(L^t_{w,e} f, \partial_{te} \mathcal{X}), \]

where \( \mathcal{X}_{te} \) and \( \partial_{te} \mathcal{X} \) have been introduced right before Lemma 5.4 (\( \partial_{te} \mathcal{X} \subset \mathcal{X} \) consists of points \( t\epsilon \)-close to the boundary of \( \mathcal{X} \), and \( \mathcal{X}_{te} = \mathcal{X} \setminus \partial_{te} \mathcal{X} \)).

By Jensen’s inequality, we have
\[ E_{w,e}(L^t_{w,e} f, \mathcal{X}_{te}) \leq 3\sigma^2_1 E_{w,e} \left( \sigma^1_1 L^t_{w,e} f, \mathcal{X}_{te} \right) + \frac{6}{c^d+2} \int_{\mathcal{X}_{te}} \int_{\mathcal{X}_{te}} (g(x)^{-r} L^t_{w,e} f(x) - g(z)^{-r} \sigma^1_1 L^t_{w,e} f(z))^2 \frac{\eta \left( \frac{\|x-z\|}{\epsilon} \right)}{g(x)^{1-q/2} g(z)^{1-q/2}} g(x) g(z) dx dz. \]

By definition (5), we have \( L^t_{w,e} f \in H^1(\mathcal{X}, g; C\|g\|_{C^{1-\eta}} M) \) for some constant \( C > 0 \), an application of Lemma 5.1 shows \( E_{w,e}(\sigma^1_1 L^t_{w,e} f, \mathcal{X}_{te}) \lesssim M^2 \). We then focus on the second term on the right-hand side of the above inequality. According to Lemma 5.4, we obtain:
\[ \frac{1}{c^d+2} \int_{\mathcal{X}_{te}} \int_{\mathcal{X}_{te}} (g(x)^{-r} L^t_{w,e} f(x) - g(z)^{-r} \sigma^1_1 L^t_{w,e} f(z))^2 \frac{\eta \left( \frac{\|x-z\|}{\epsilon} \right)}{g(x)^{1-q/2} g(z)^{1-q/2}} g(x) g(z) dx dz \]
\[ \lesssim \frac{1}{c^d+2} \int_{\mathcal{X}_{te}} \int_{\mathcal{X}_{te}} g(x)^{p+r} (g(x)^{-r} L^t_{w,e} f(x) - g(z)^{-r} \sigma^1_1 L^t_{w,e} f(x))^2 \eta \left( \frac{\|x-z\|}{\epsilon} \right) dx dz \]
\[ \lesssim \frac{1}{c^d+2} \int_{\mathcal{X}_{te}} g(x)^{p-r} (L^t_{w,e} f(x) - \sigma^1_1 L^t_{w,e} f(x))^2 dx \]
\[ \lesssim M^2. \]

Furthermore, near the boundary, according to Lemma 5.3 and Lemma 5.5, it yields that
\[ E_{w,e}(L^t_{w,e} f, \partial_{te} \mathcal{X}) \leq \frac{1}{c^d+2} ||L^t_{w,e} f||_{L^2(\partial_{te} \mathcal{X}, g^{p+r})} \lesssim M^2. \]

Putting all pieces above together, we obtain the proof for the case when \( s \) is odd and \( t := (s-1)/2 \). Similar arguments can be applied to the case when \( s \) is even and \( t := (s-2)/2 \). Therefore, combining all above together, we obtain for all integer \( s > 1 \):
\[ \langle L^t_{w,e} f, f \rangle_{g^{p-r}} \lesssim M^2. \]

We are now in the position to prove the main results of Section 3.2.

**Proof of Theorem 3.1.** By Cauchy-Schwarz inequality, we have: for all \( s \in \mathbb{N}_+ \):
\[ \| \hat{f} - f \|^2_{w,n} \leq 2(\| \hat{E} \hat{f} - f \|^2_{w,n} + \| \hat{f} - E \hat{f} \|^2_{w,n}). \]

Then, according to PCR-WLE algorithm in Section 2.2, we obtain
\[ \| \hat{E} \hat{f} - f \|^2_{w,n} = \sum_{k=K+1}^{n} \langle v_k, f \rangle^2_{w,n} \leq \frac{\langle L^t_{w,e} f, f \rangle_{w,n}}{\lambda_{K+1}^n}, \quad (24) \]
We would like to point out here that the normalization factor is needed to scale $\eta \left( \frac{\|X_i - X_j\|}{\epsilon} \right)$ and the remaining factor, $\epsilon^{-2}$, stabilized the squared differences of $d_i^{-\frac{1}{2}}$ under the expectation.

According to Section 6.1 and by conditioning on $X_i$ and the law of iterated expectation, we have for $n$ large enough,

$$\left| \mathbb{E} \left( \frac{1}{\epsilon^{d+2}} \left| d_i^{-\frac{1}{2}} f(X_i) - d_j^{-\frac{1}{2}} f(X_j) \right|^2 \right) - 2 \langle L_{w,n} f, f \rangle_{g^{d-r}} \right| \lesssim \Delta(n, \epsilon, \eta, g) + \epsilon,$$

with probability at least $1 - e^{-K}$ if $1 \leq K \leq n$. Then, it remains to bound the empirical weighted Sobolev seminorm $\langle L_{w,n} f, f \rangle_{w,n}$ and the graph weighted Laplacian eigenvalue $\lambda_{K+1}$.

We will first focus on $\langle L_{w,n,s} f, f \rangle_{w,n}$ for $s = 1$. By definition (4), we have by symmetry:

$$\mathbb{E}(L_{w,n,s} f, f)_{w,n} = \frac{1}{2} \mathbb{E} \left( \frac{1}{\epsilon^{d+2}} \left| d_i^{-\frac{1}{2}} f(X_i) - d_j^{-\frac{1}{2}} f(X_j) \right|^2 \right).$$
where
\[
\Delta(n, \epsilon, \eta, g) := \frac{1}{n} g_{\text{max}} + \frac{\eta(0)}{ne^2} + \frac{n - 1}{n} \left( \sqrt{\frac{\log \epsilon}{n \epsilon^2}} + \epsilon \right) \to 0 \quad \text{as } n \to \infty.
\]

Combining (29), (30) and Lemma 5.1, we obtain:
\[
\mathbb{E}(L_{w,n,\epsilon} f, f)_{w,n} \lesssim M^2 + \Delta(n, \epsilon, \eta, g) + \epsilon.
\]

Consequently, by Markov’s inequality, we have: for any \(\delta \in (0, 1)\),
\[
\langle L_{w,n,\epsilon} f, f \rangle_{w,n} \lesssim \frac{1}{\delta} \left( M^2 + \Delta(n, \epsilon, \eta, g) + \epsilon \right),
\]
with probability at least \(1 - \delta\). Note that the above bound on the expected weighted Sobolev seminorm generalizes the results in Green et al. (2023) to the weighted Laplacians by some properties of KDE.

Next, we proceed to the higher order case when \(s > 1\) for \(L_{w,n,\epsilon}^s f, f\) \(w,n\). We define the following difference operator:
\[
D_j f(x) = (d_i^+ w_{i,j} x - d_i^- w_{i,j} f(x)) d_i^{-\frac{p-1}{q}} w_{i,j},
\]
where \(d_i\) and \(w_{i,j}\) are defined by replacing \(X_i\) by \(x\) in both \(d_i\) and \(w_{i,j}\). Furthermore, let \(D_j f(x) := (D_j f \circ \ldots \circ D_j f)(x)\), where \(j = (j_1, \ldots, j_s) \in \mathbb{N}^s := \{1, \ldots, n\}^s\). Denote by \((n)^s\) the sub-collection of vectors in \(\mathbb{N}^s\) with no repeated indices and let by \(ij := (i, j_1, j_2, \ldots, j_s)\).

Following the idea of Green et al. (2023, Proof of Lemma 3), we decompose the weighted Sobolev seminorm into a U-statistic, which is an unbiased estimator of the non-local Sobolev seminorm \(L_{w,n,\epsilon}^s f, f\) \(g^{p-r}\), and a pure bias term:
\[
\langle L_{w,n,\epsilon}^s f, f \rangle_{w,n} = \frac{1}{n} \sum_{i=1}^{n} d_i^{-\frac{p-1}{q}} L_{w,n,\epsilon}^s f(X_i) \cdot f(X_i)
\]
\[
= \frac{1}{ne^{2s}} \sum_{ij \in (n)^{s+1}} d_i^{-\frac{p-1}{q-r}} D_j f(X_i) \cdot f(X_i)
\]
\[
+ \frac{1}{ne^{2s}} \sum_{ij \in (n)^{s+1}} d_i^{-\frac{p-1}{q-r}} D_j f(X_i) \cdot f(X_i)
\]
\[
=: I_1 + I_2.
\]

Note that there are errors in Green et al. (2023, Proof of Lemma 3) when bounding both \(\mathbb{E} I_1\) and \(\mathbb{E} I_2\). Specifically, in Green et al. (2023, Lemma D.3), there should not be a \(\delta\) appearing in Equation D.4 by Markov’s inequality and the power of \(\epsilon\) should be \(2s + d\). Although their final result is correct, we will fix these errors in the following proof.

Now, determined by whether all \(ij\) are distinct, the empirical weighted Sobolev seminorm can be divided into two parts, \(I_1\) and \(I_2\). The first one involves all distinct indices where we make approximation by the so-called non-local weighted sobolev norm \(\langle L_{w,n,\epsilon}^s f, f \rangle_{g^{p-r}}\); the second part focuses on the case where not all \(ij\) are distinct and use the fact that it is related to a connected subgraph.

As for \(I_1\) from (32), we have
\[
\mathbb{E} I_1 = \frac{1}{ne^{2s}} \frac{n!}{(n-s-1)!} \mathbb{E} \left( d_i^{-\frac{p-1}{q-r}} D_j f(X_i) \cdot f(X_i) \right)
\]
\[
= \frac{1}{ne^{2s}} \frac{n!}{(n-s-1)!} \mathbb{E} \langle D_j f(X_i), f(X_i) \rangle_{g^{p-r}},
\]
where the operator \(D_j\) is iterated for \(s\) different times due to the fact that \(ij\) are all distinct. For each iteration, say \(s = 1\), we have
\[
\mathbb{E} \langle D_j f(X_i), f(X_i) \rangle_{g^{p-r}}
\]
The Stirling’s formula shows
\[ E \sim \frac{1}{2n} \left( \frac{1}{e} + \frac{1}{2} \right)^{n-1/2} \frac{\sqrt{2\pi n}}{e^{n}}. \]

After \( s \) times iteration, it yields that
\[ \| E_g \|_{p-\rho} \leq \frac{\epsilon^2}{2n} (\Delta(n, \epsilon, g) + \epsilon). \]

Putting all above results back in \( \mathbb{E} I_1 \), we conclude that for \( n \) large enough,
\[ \mathbb{E} I_1 \lesssim \left( \frac{\epsilon^2}{2n} (\Delta(n, \epsilon, g) + \epsilon). \right) \]

The Stirling’s formula shows
\[ \lim_{n \to \infty} \frac{n!}{n^{s+1}(n-s-1)!} = 1. \]

Therefore, by (34), we have for \( n \) large enough,
\[ \mathbb{E} I_1 \lesssim \left( \frac{\epsilon^2}{2n} (\Delta(n, \epsilon, g) + \epsilon). \right) \]

According to Lemma 5.6, it yields that
\[ \mathbb{E} I_1 \lesssim M^2 + (\Delta(n, \epsilon, g) + \epsilon). \]

We next shift our attention to \( I_2 \) in (32):
\[ \frac{1}{n^{s+2}} \sum_{ij \in [n]^{s+1} \setminus [n]^{s+1}} \frac{1}{n^{s+2}} D_3 f(X_i) \cdot (f(X_i) - f(X_{ji})). \]

For \( ij \) not distinctive, if they contains a total of \( (k + 1) \) distinct indices for example for \( 1 \leq k \leq s - 1 \), we have by symmetry:
\[ \sum_{ij \in [n]^{s+1} \setminus [n]^{s+1}} \frac{1}{n^{s+2}} D_3 f(X_i) \cdot (f(X_i) - f(X_{ji})). \]

Observe that in order for
\[ \frac{1}{n^{s+2}} |D_3 f(X_i)| \cdot |f(X_i) - f(X_{ji})| \]
to be non-zero, it must be the case that the graph \( G_{n, s}(X_{ij}) \) which is the subgraph induced by the vertices \( X_i, X_{j_1}, \ldots, X_{j_s} \) is complete. Since we have:
\[ D_{ij} f(x) = D_i(D_{ij} f(x)) \]
\[ = D_i \left( d_{i}^{-\frac{1}{s+1}} f(x) - d_{j}^{-\frac{1}{s+1}} f(x_{j}) \right)^{s+1} w_{i, j}^{s+1} \]

then
\[ |D_{j_1 \ldots k} f(X_i)| \leq \left( d_{i}^{-\frac{1}{s+1}} |D_{ij} f(X_i)| + d_{j}^{-\frac{1}{s+1}} |D_{j_1 \ldots k} f(X_{j_1})| \right)^{s+1} w_{i, j}. \]
Repeating the above computation and by induction, it yields that for \( s \geq 2, \)

\[
|D_j f(X_i)| \leq (s - 1) d_i^{\frac{1}{s-1}} \max_{j \in \mathcal{J}} |D_{ij} f(X_i)| \cdot |f(X_i) - f(X_{j_i})| \cdot \mathbf{1}_{\{G_{n,\epsilon}(X_{j_i}) \text{ is connected}\}}
\]

where \( d_{\max} := \max_{i=1,\ldots,n} d_i, \) \( d_{\min} := \min_{i=1,\ldots,n} d_i, \) \( w_{\max} := \max_{i,j=1,\ldots,n} w_{i,j} \) and \( d_{\max}/d_{\min} \) means it is \( d_{\max} \) if \(- (s - 1)r/(d - 1)\) (respectively \((s - 1)(1-p)/(q - 1)\)) are positive and it is \( d_{\min} \) otherwise.

According to Section 6.1, we have for \( n \) large enough, \( d_{\max} \) is bounded from above and \( d_{\min} \) is bounded from below a.s. and

\[
w_{\max} \lesssim \frac{1}{n^{d+2}},
\]

almost surely.

Consequently, it yields that

\[
\begin{align*}
&d_i^{\frac{1}{s-1}} \max_{j \in \mathcal{J} \setminus \{j_i\}} |D_j f(X_i)| \cdot |f(X_i) - f(X_{j_i})| \\
&= d_i^{\frac{1}{s-1}} |D_j f(X_i)| \cdot |f(X_i) - f(X_{j_i})| \cdot \mathbf{1}_{\{G_{n,\epsilon}(X_{j_i}) \text{ is connected}\}} \\
&\lesssim \frac{1}{n^{d+2}} \sum_{j \in \mathcal{J} \setminus \{j_i\}} \left( d_i^{\frac{1}{s-1}} |D_j f(X_i)| \cdot |f(X_i) - f(X_{j_i})| \cdot \mathbf{1}_{\{G_{n,\epsilon}(X_{j_i}) \text{ is connected}\}} \right) \\
&= \frac{e^2}{n^{d+2}} \sum_{j \in \mathcal{J} \setminus \{j_i\}} \left( \frac{1}{e^{d+2}} d_i^{\frac{1}{s-1}} |D_j f(X_i)| \cdot |f(X_i) - f(X_{j_i})| d_j^{\frac{1}{s-1}} \eta \left( \frac{\|X_i - X_{j_i}\|}{\epsilon} \right) \right),
\end{align*}
\]

where we again assign \( \epsilon^{d+2} \) as a normalization factor into the expectation as \( (29) \).

Now, note that for \( j = i \) in the summand on the right-hand side of \( (36) \), we have according to Section 6.1:

\[
\begin{align*}
&\mathbb{E} \left( \frac{1}{e^{d+2}} d_i^{\frac{1}{s-1}} |d_i^{\frac{1}{s-1}} f(X_i) - d_j^{\frac{1}{s-1}} f(X_{j_i})| \eta \left( \frac{\|X_i - X_{j_i}\|}{\epsilon} \right) d_i^{\frac{1}{q-2}} d_j^{\frac{1}{q-2}} |f(X_i) - f(X_{j_i})| \right) \\
&\quad \cdot \mathbf{1}_{\{G_{n,\epsilon}(X_{j_i}) \text{ is connected}\}} \\
&\lesssim \mathbb{E} \left( \left( \frac{1}{e^{d+2}} |d_i^{\frac{1}{s-1}} f(X_i) - d_j^{\frac{1}{s-1}} f(X_{j_i})| \eta \left( \frac{\|X_i - X_{j_i}\|}{\epsilon} \right) d_i^{\frac{1}{q-2}} d_j^{\frac{1}{q-2}} |f(X_i) - f(X_{j_i})| \right) \\
&\quad \cdot \mathbf{1}_{\{G_{n,\epsilon}(X_{j_i}) \text{ is connected}\}} \right) \\
&\quad \lesssim \mathbb{E} \left( \left( \frac{1}{e^{d+2}} |d_i^{\frac{1}{s-1}} f(X_i) - d_j^{\frac{1}{s-1}} f(X_{j_i})|^2 \eta \left( \frac{\|X_i - X_{j_i}\|}{\epsilon} \right) d_i^{\frac{1}{q-2}} d_j^{\frac{1}{q-2}} |f(X_i) - f(X_{j_i})| \right) \\
&\quad \cdot \mathbf{1}_{\{G_{n,\epsilon}(X_{j_i}) \text{ is connected}\}} \right),
\end{align*}
\]

where the last inequality is by Cauchy–Schwarz inequality and \( X_1, \ldots, X_n \) being i.i.d. data. Then, by integrating out all indices in \( j \) not equal to \( i \) or \( j_i \), it yields that

\[
\mathbb{E} \left( \left( \frac{1}{e^{d+2}} |d_i^{\frac{1}{s-1}} f(X_i) - d_j^{\frac{1}{s-1}} f(X_{j_i})|^2 \eta \left( \frac{\|X_i - X_{j_i}\|}{\epsilon} \right) d_i^{\frac{1}{q-2}} d_j^{\frac{1}{q-2}} |f(X_i) - f(X_{j_i})| \right) \\
\quad \cdot \mathbf{1}_{\{G_{n,\epsilon}(X_{j_i}) \text{ is connected}\}} \right),
\]
\( \mathbf{1}_{\{G_{n,\epsilon}(X_{ij}) \text{ is connected}\}} \)
\[
\lesssim (C\epsilon^d g_{\max} V_d)^{k-1} \mathbb{E} \left( \frac{1}{\epsilon^{d+2}} |d_i^{-\frac{r}{d}} f(X_i) - d_j^{-\frac{r}{d}} f(X_j)|^2 \frac{\eta (\|X_i - X_j\|)}{d_i^{1-\eta} d_j^{1-\eta}} \right)
+ (\Delta(n, \epsilon, \eta, g) + \epsilon) \right) .
\]  

(38)

Therefore, according to (37), (38), (30) and Lemma 5.1, we obtain
\[
\mathbb{E} \left( \frac{1}{\epsilon^{d+2}} |d_i^{-\frac{r}{d}} f(X_i) - d_j^{-\frac{r}{d}} f(X_j)|^2 \frac{\eta (\|X_i - X_j\|)}{d_i^{1-\eta} d_j^{1-\eta}} |f(X_i) - f(X_j)| \right)
\mathbf{1}_{\{G_{n,\epsilon}(X_{ij}) \text{ is connected}\}} \lesssim \epsilon^{d(k-1)} \left( M^2 + \Delta(n, \epsilon, \eta, g) + \epsilon \right) .
\]  

(39)

Applying a similar approach to all \( j \neq j_s \) and plugging (39) in (36) and (32), we have
\[
\mathbb{E} I_2 \lesssim \frac{1}{n^{2s}} \frac{1}{\epsilon^{d(s-1)}} \sum_{k=1}^{s-1} \epsilon^{d(k-1)} \left( M^2 + \Delta(n, \epsilon, \eta, g) \right) n^{k+1}
\lesssim \frac{\epsilon^2}{n^{2s}} \left( M^2 + \Delta(n, \epsilon, \eta, g) + \epsilon \right) \sum_{k=1}^{s-1} \frac{(n \epsilon^d)^k}{(n \epsilon^d)^s} n .
\]

Note that the above sum is bounded from above when \( k = s - 1 \) by the assumption \( n \epsilon^d \geq 1 \). Finally, we conclude that
\[
\mathbb{E} I_2 \lesssim \frac{\epsilon^2}{n^{2s+d}} \left( M^2 + \Delta(n, \epsilon, \eta, g) + \epsilon \right) .
\]  

(40)

Finally, combining (32), (35) and (40), we obtain:
\[
\mathbb{E} \langle L^s_{w, n, \epsilon, f, f} \rangle_{w, n} \lesssim M^2 + (\Delta(n, \epsilon, \eta, g) + \epsilon) + \frac{\epsilon^2}{n^{2s+d}} \left( M^2 + \Delta(n, \epsilon, \eta, g) + \epsilon \right)
\lesssim M^2 + (\Delta(n, \epsilon, \eta, g) + \epsilon) ,
\]

where the last step is by the assumption that \( \epsilon \gtrsim n^{-1/(2(s-1)+d)} \). By Markov’s inequality, we have for any \( \delta \in (0, 1) \),
\[
\langle L^s_{w, n, \epsilon, f, f} \rangle_{w, n} \lesssim \frac{1}{\delta} \left( M^2 + (\Delta(n, \epsilon, \eta, g) + \epsilon) \right) ,
\]  

(41)

with probability at least \( 1 - 2\delta \). This bound can be considered as a higher order variant of (31) for \( s > 1 \).

Now, recall the bound (28). We have bounded the empirical weighted Sobolev seminorm by (31) and (41). It remains to bound the eigenvalues \( \lambda_{K+1} \).

According to Lemma 6.1, we have:
\[
\lambda_k = \lambda_k(L_{w, n, \epsilon}) \gtrsim \lambda_k(L_w) \wedge \epsilon^2 , \text{ for all } 2 \leq k \leq n ,
\]  

(42)

with probability at least \( 1 - C n \epsilon^{-cn} \) for some constants \( C, c > 0 \).

For \( s = 1 \), combining (28), (31) and (42), we have with probability at least \( 1 - \delta - C n \epsilon^{-cn} - \epsilon^{-K} \) and \( n \) large enough:
\[
\| \hat{f} - f \|_{w, n} \lesssim \frac{M^2}{\delta (\lambda_{K+1}(L_w) \wedge \epsilon^2)} + \frac{K}{n} .
\]
Furthermore, based on the assumption $\epsilon \lesssim K^{-1/d}$ and Proposition 6.6, the above inequality becomes:

$$\| \hat{f} - f \|^2_{w,n} \lesssim \frac{M^2}{\delta} (K + 1)^{-2/d} + \frac{K}{n}. \quad (43)$$

By balancing the two terms on the right-hand side, we pick $K$.

Furthermore, based on the assumption $\epsilon \lesssim K^{-1/d}$, therefore, according to Theorem 3.1, we have: for any $s$, \( \epsilon \lesssim 1/n^d \),

$$\| \hat{f} - f \|^2_{w,n} \lesssim \frac{1}{\delta} M^2 (M^2 n)^{-2/(2+d)}. \quad (44)$$

If $M^2 < n^{-1}$, we can take $K = 1$ and obtain from (43) that:

$$\| \hat{f} - f \|^2_{w,n} \lesssim \frac{1}{n^d}.$$

If $M > n^{1/d}$, we take $K = n$ and in this case, we actually have $\hat{f}(X_i) = Y_i$ for $i = 1, \ldots, n$ and

$$\| \hat{f} - f \|^2_{w,n} = \frac{1}{n} \sum_{i=1}^{n} \epsilon_i^2 \lesssim C,$$

with probability at least $1 - e^{-n}$ for some constant $C$. Combining all above cases depending on choices of $K$, it yields that bound in Theorem 3.1.

For $s > 1$, the proof follows in a similar way by considering (41) instead of (31).

\[ \square \]

5.2 Proof Of Theorem 3.2

Proof of Theorem 3.2. Recall the construction of the estimator based on Lepski’s procedure: $\hat{f}_{\text{adapt}} = \hat{f}_{\text{opt},M}$ with $\hat{s}, \hat{M}$ given in Section 3.3. Let the event $E_j$ be that $\hat{s} = s_j$ and suppose $s = s_i$ for the true smooth parameter.

First of all, it suffices to consider $M \in D$ by realizing that if $M \in (M_{j-1}, M_j)$, then $f \in H^s(X, g; M)$ with $H^s(X, g; M_{j-1}) \subset H^s(X, g; M) \subset H^s(X, g; M_j)$. Now, we also suppose $M = M_i$ correspondingly and consider bounding the sum:

$$\sum_{j=1}^{N_i} \left( \| \hat{f}_{s_j} - f \|^2_{w,n} M_i^{-2} (M_i^2 n/ \log n)^{2s_i/(2s_i + d)} 1_{E_j} \right),$$

conditional on the event that the sample points $X_1, \ldots, X_n$ satisfy (28) and (42) with $K = [M_i^2 n]^{d/(2s_i + d)}$. These two statements hold with probability at least $1 - C n e^{-Cn} - e^{-[M_i^2 n]^{d/(2s_i + d)}}$. As we will see, the fact that this sum does not explode, relies on the fact that the probabilities of the sets $E_j$ get small as $n \rightarrow \infty$.

First, note that by Cauchy-Schwarz inequality, we have

$$\sum_{j=1}^{N_i} \left( \| \hat{f}_{s_j} - f \|^2_{w,n} M_i^{-2} (M_i^2 n/ \log n)^{2s_i/(2s_i + d)} 1_{E_j} \right)$$

$$\leq \sum_{j=1}^{N_i} \left( \| \hat{f}_{s_j} - \hat{f}_{s_j} + \hat{f}_{s_j} - f \|^2_{w,n} M_i^{-2} (M_i^2 n/ \log n)^{2s_i/(2s_i + d)} 1_{E_j} \right)$$

$$\leq \sum_{j=1}^{N_i} \left( 2 \epsilon_i^2 1_{E_j} + 2 \left( \| \hat{f}_{s_j} - f \|^2_{w,n} M_i^{-2} (M_i^2 n/ \log n)^{2s_i/(2s_i + d)} 1_{E_j} \right) \right)$$

$$\leq 2 \epsilon_i^2 + 2 \left( \| \hat{f}_{s_j} - f \|^2_{w,n} M_i^{-2} (M_i^2 n/ \log n)^{2s_i/(2s_i + d)} 1_{E_j} \right).$$

Therefore, according to Theorem 3.1, we have: for any $\delta \in (0, 1)$,

$$\sum_{j=1}^{N_i} \left( \| \hat{f}_{s_j} - f \|^2_{w,n} M_i^{-2} (M_i^2 n/ \log n)^{2s_i/(2s_i + d)} 1_{E_j} \right) \lesssim \frac{1}{\delta},$$
with probability at least $1 - \delta \log^{-2s_i/(2s_i+d)} n - C_1 n e^{-C_2 (2s_i+d)}$. 

Next, we consider the other part when $j < i$:

$$\sum_{j=1}^{i-1} \left( \left\| \hat{f}_{s_j} - f \right\|_{w,n}^2 M_i^{-2} (M_i^2 n/\log n)^{2s_i/(2s_i+d)} \mathbf{1}_{E_j} \right).$$

By the definition, on the event $E_j$, there exists $s' \in \mathcal{B}$ with $s' < s_i$ such that $\left\| \hat{f}_{s_j} - f \right\|_{w,n} > c_0 M_i^{-2} (M_i^2 n/\log n)^{-s'/(2s_i+d)}$. This means $\left\| \hat{f}_{s_i} - \hat{f}_{s'} \right\|_{w,n}^2 M_i^{-2} (M_i^2 n/\log n)^{2s_i/(2s_i+d)} > c_0^2$. By triangle inequality, this implies we have either $\left\| \hat{f}_{s_i} - f \right\|_{w,n} M_i^{-2} (M_i^2 n/\log n)^{2s_i/(2s_i+d)} > c_0^2/4$ or $\left\| \hat{f}_{s'} - f \right\|_{w,n} M_i^{-2} (M_i^2 n/\log n)^{2s'/(2s_i+d)} > c_0^2/4$. Then, we have

$$\mathbb{P}(E_j) \leq \sum_{l=1}^{i-1} \left( \mathbb{P} \left( \left\| \hat{f}_{s_i} - f \right\|_{w,n}^2 M_i^{-2} (M_i^2 n/\log n)^{2s_i/(2s_i+d)} > c_0^2/4 \right) \right) + \mathbb{P} \left( \left\| \hat{f}_{s_i} - f \right\|_{w,n} M_i^{-2} (M_i^2 n/\log n)^{2s_i/(2s_i+d)} > c_0^2/4 \right).$$

Since $l < i$, we have $f \in H^{s_i}(X, g; M_i) \subset H^{s_i}(X, g; M_l)$ for all $l < i$. Therefore, it suffices to focus on the concentration inequality of $\hat{f}_{s_i}$ to $f$, i.e., bounding

$$\mathbb{P} \left( \left\| \hat{f}_{s_i} - f \right\|_{w,n}^2 M_i^{-2} (M_i^2 n/\log n)^{2s_i/(2s_i+d)} > c_0^2/4 \right).$$

Note that the key problem here is the rate of convergence of $\left\| \hat{f}_{s_i} - f \right\|_{w,n}$ in (45) does not match the rate $(n/\log n)^{2s_i/(2s_i+d)}$ given there. However, this can be dealt with by controlling the probability of the event $E_j$.

The strategy here is we need a better concentration inequality than what has been proven previously as (41) otherwise the probability of the event $E_j$ will not decay to 0. Observe that the concentration (41): for $n$ large enough and with probability smaller than $1 - 2\delta$, 

$$\langle L_{w,n,s}^* f, f \rangle_{w,n} \lesssim \delta^{-1} M^2,$$

is from the application of Markov’s inequality with 

$$\mathbb{E}(L_{w,n,s}^* f, f)_{w,n} \lesssim M^2,$$

for $n$ large enough. While bounding the first moment gives a concentration inequality with probability $1 - 2\delta$, establishing a higher moment bound, e.g. the second moment, would result in a better concentration inequality with higher probability similar to Green et al. (2021, Proposition 1), which fits in our proof technique.

Starting with $s = 1$ and similar to (30), we have: for $n$ large enough,

$$\text{Var}(L_{w,n,1}^* f, f)_{w,n} \lesssim \text{Var} \left( \frac{1}{2} \frac{1}{n^2 e^{d+2}} \sum_{i,j=1}^{n} (g(X_i)^{-r} f(X_i) - g(X_j)^{-r} f(X_j))^2 g(X_i)^{1-p} \frac{\eta \left( \frac{\|X_i - X_j\|}{\varepsilon} \right)}{g(X_i)^{1-q/2} g(X_j)^{1-q/2}} \right).$$

For $i, j \in 1, \ldots, n$, let

$$V_{ij} := (g(X_i)^{-r} f(X_i) - g(X_j)^{-r} f(X_j))^2 g(X_i)^{1-p} \frac{\eta \left( \frac{\|X_i - X_j\|}{\varepsilon} \right)}{g(X_i)^{1-q/2} g(X_j)^{1-q/2}}.$$

We have:

$$\text{Var} \left( \sum_{i,j=1}^{n} (g(X_i)^{-r} f(X_i) - g(X_j)^{-r} f(X_j))^2 g(X_i)^{1-p} \frac{\eta \left( \frac{\|X_i - X_j\|}{\varepsilon} \right)}{g(X_i)^{1-q/2} g(X_j)^{1-q/2}} \right) \lesssim \sum_{i,j=1}^{n} V_{ij} \lesssim M^2.$$
Now, returning to our mission (47), by setting $\delta$ holds with probability not less than $1 - \epsilon$.

\[
\text{Var}(L_{w,n,\epsilon}f, f)_{w,n} \lesssim \frac{1}{n^4} \epsilon^{2d+4} \left( n^3 \epsilon^{2d+4} M^4 + n^2 \epsilon^{d+4} M^4 \right) \lesssim n^{-1} M^4,
\]

where the last step follows by the assumption that $ne^d \geq 1$. Then, by Markov’s inequality, we obtain: for any $\delta \in (0, 1)$,

\[
\mathbb{P} \left( \left| (L_{w,n,\epsilon}f, f)_{w,n} - \mathbb{E}(L_{w,n,\epsilon}f, f)_{w,n} \right| \geq \frac{1}{\delta} M^2 \right) \leq \frac{\delta^2}{n}. \tag{49}
\]

Combining (49) and (31), we conclude that for $n$ large enough,

\[
(L_{w,n,\epsilon}f, f)_{w,n} \lesssim \frac{1}{\delta} M^2
\]

holds with probability not less than $1 - \frac{\delta}{n^2}$. Furthermore, following a similar argument in Lemma 5.6, one can show the above high-probability bound also holds for the case $s > 1$. Thus, under the additional Lipschitz assumption that $|f_p(x) - f_p(x')| \leq M |x - x'|$, we establish a better bound for the empirical weighted Sobolev seminorm: for all $s \in \mathbb{N}_+$ and $n$ large enough,

\[
(L^s_{w,n,\epsilon}f, f)_{w,n} \lesssim \frac{1}{\delta} M^2,
\]

with probability at least $1 - C \frac{s^2}{n}$.

Conditional on the event that the sample points $X_1, \ldots, X_n$ satisfy (28) and (42) with $K = [M^2 n]^{d/(2s+d)}$, following the proof of Theorem 3.1 to obtain (44) by using the better concentration inequality we derived above, we have for $n$ large enough, 

\[
\|\hat{f} - f\|_{w,n,\epsilon}^2 \lesssim \frac{1}{\delta} M^2 (M^2 n)^{-2s/(2s+d)},
\]

with probability at least $1 - C \frac{s^2}{n} - Cne^{-Cn^e} - e^{-[M^2 n]^{d/(2s+d)}}$ under the minimax optimal setting for $M$.

Now, returning to our mission (47), by setting $\delta = \epsilon_0^2/4 \cdot \log^{2s/(2s+d)} n$, we have:

\[
\mathbb{P} \left( \|\hat{f}_s - f\|_{w,n,\epsilon}^2 M^{-2} (M^2 n/ \log n)^{2s/(2s+d)} > \epsilon_0^2/4 \right) \leq 16C \epsilon_0^4 n^{-1} \log^{-2s/(2s+d)} n + Cne^{-Cn^e} + e^{-[M^2 n]^{d/(2s+d)}}.
\]
With (46), we obtain:
\[ \mathbb{P}(\mathcal{E}_j) \leq 16C_0^{-4}n^{-1} \log^{1-2s_{\min}/(2s_{\min}+\delta)} n + CnCn^{d/\log n} n + e^{-\lfloor \frac{2s_{\min}n}{2s_{\min}+d} \rfloor/2} \log n. \]
Combining the above result with (45) and noting that on \( \mathcal{E}_j^c \), \( 1 \mathbb{E}_j = 0 \), it yields that
\[ \sum_{j=1}^{i-1} \left( \left\| \hat{f}_{s,j} - f \right\|^2_{\omega,n} M_i^{-2} (M_i^2 n/\log n)^{2s_{\min}/(2s_{\min}+d)} 1_{\mathcal{E}_j} \right) \lesssim \frac{1}{\delta}, \]
with probability at least
\[ 1 - \delta \log^{2s_{\min}/(2s_{\min}+d)} n - 16C_0^{-4}n^{-1} \log^{2-2s_{\min}/(2s_{\min}+d)} n - CnCn^{d/\log n} n - e^{-\lfloor \frac{2s_{\min}n}{2s_{\min}+d} \rfloor/2} \log^2 n. \]

6 AUXILIARY RESULTS

In the subsequent two sections, we introduce some important properties of KDE and eigenvalues of the weighted Laplacian matrices \( L_{w,n,\epsilon} \) and the weighted Laplacian operators \( L_w \) used in the previous proof respectively.

6.1 Property Of Kernel Density Estimation

Consider a Kernel density estimator (KDE) on \( \mathcal{X} \):
\[ g_n(x) := \frac{1}{n\epsilon^d} \sum_{j=1}^{n} \eta \left( \frac{\|x - X_j\|}{\epsilon} \right), \]
where \( \eta \) is a kernel function.

In Giné and Guillou (2002), it has been proven that the above KDE satisfies the following almost sure convergence:
\[ \|g_n(x) - \mathbb{E}g_n(x)\|_\infty = O_{a.s.} \left( \sqrt{\frac{\log \epsilon}{n\epsilon^d}} \right), \]
given the assumption that the kernel \( \eta \) satisfies the kernel VC-type condition (A4) and see Remark 3.2 for more details.

As for the bias, it is well-known that there exists a boundary effect on KDE due to the fact that (with probability 1) all the samples lie in the support of the density. However, when we are far enough away from the boundary such that \( B_x(\epsilon) \subset \mathcal{X} \), we have
\[ \mathbb{E}g_n(x) - g(x) \leq \frac{\epsilon}{\|x\|^{\frac{2s_{\min}}{2s_{\min}+\delta}}} g(x) - g(x) \]
\[ \leq \frac{\epsilon}{\|z\|^{\frac{2s_{\min}}{2s_{\min}+\delta}}} \eta(\|z\|) g(x + \epsilon z) - g(x) \|z\| \]
\[ \lesssim \epsilon \int_{|z| \leq 1} \|z\| \eta(\|z\|) d\|z\| \lesssim \epsilon, \]
where the last step is by the assumption that \( g \) is Lipschitz. As a result, for such values of \( x \),
\[ \|g_n(x) - g(x)\|_\infty = O_{a.s.} \left( \sqrt{\frac{\log \epsilon}{n\epsilon^d}} + \epsilon \right). \]

When \( x \) is near the boundary, i.e., \( B_x(\epsilon) \not\subset \mathcal{X} \), we have \( X_i \in B_x(\epsilon) \) with probability less than \( C \epsilon \) for some constant \( C > 0 \). Then:
\[ \mathbb{E}g_n(x) \leq \max_{|z| \leq 1} \eta(\|z\|) d\|z\| < \infty, \]
and
\[ E g_n(x) = \int_{\{\|z\| \leq 1\} \cap \{x + \epsilon z \in \mathcal{X}\}} \eta(\|z\|) g(x + \epsilon z) dz \geq g_{\min} \int_{\{\|z\| \leq 1\} \cap \{x + \epsilon z \in \mathcal{X}\}} \eta(\|z\|) dz > 0, \]
under the assumption (A1) on $\mathcal{X}$. Therefore, we have for all $x \in \mathcal{X}$, $g_n(x)$ is bounded from above and below a.s. for $n$ large enough.

By conditioning on $X_i$ and the law of total probability, we have for all $i \in [n]$ and $B_\epsilon(X_i) \in \mathcal{X}$,
\[ \Delta^-(n, \epsilon, \eta, g) \leq g_n(X_i) - g(X_i) \leq \Delta^+(n, \epsilon, \eta, g), \]
almost surely with
\[ \Delta^-(n, \epsilon, \eta, g) := -\frac{1}{n} g_{\max} + \frac{\eta(0)}{n \epsilon^d} - \frac{n - 1}{n} \Delta(n, \epsilon), \]
\[ \Delta^+(n, \epsilon, \eta, g) := -\frac{1}{n} g_{\min} + \frac{\eta(0)}{n \epsilon^d} + \frac{n - 1}{n} \Delta(n, \epsilon), \]
and
\[ \Delta(n, \epsilon) := \sqrt{\frac{\log \epsilon}{n \epsilon^d}} + \epsilon. \]

Since we are seeking a high-probability bound in Theorems 3.1, it is not necessarily required to have an exact estimation near the boundary, which happens with probability of the order $\epsilon$. However, various approaches including data reflection, transformations, boundary kernels and local likelihood, have been proposed for boundary correction.

### 6.2 Property Of Eigenvalues

In this section, we focus on introducing some results on the eigenvalues of the weighted Laplacian $L_{n, w, \epsilon}$ and the weighted Laplacian operator $L_w$ based on analysis in Calder and Trillos (2022), Green et al. (2021).

#### 6.2.1 Transportation Distance Between Measures

For a probability measure $G$ defined on $\mathcal{X}$ and a map $T : \mathcal{X} \to \mathcal{X}$, denote by $T_\sharp G$ the push-forward of $G$ by $T$, i.e., the measure such that for any Borel subset $U \subseteq \mathcal{X}$, it holds that
\[ T_\sharp G(U) := G(T^{-1}(U)). \]

When $T_\sharp G$ is taken as the empirical measure of $G$ denoted by $G_n$, $T$ is called the transportation map between $G$ and $G_n$ and we define the $\infty$-transportation distance between $G$ and $G_n$ as
\[ d_\infty(G, G_n) := \inf_{T : T_\sharp G = G_n} \|T - \text{Id}\|_{L^\infty(G)}, \quad (50) \]
where $\text{Id}$ is the identity mapping. We denote by $\tilde{T}$ the optimal $\infty$-optimal transport map ($\infty$-OT map) between $G$ and $G_n$, i.e., the map that achieves the infimum (50).

Now, following Green et al. (2021), let
\[ \tilde{\delta} := \max\{n^{-1/d}, C \epsilon\}, \]
where $C > 0$ is some constant not depending on $n$ and we also let $\theta > 0$ be some constant not depending on $n$. We present the following result from Green et al. (2021).

**Proposition 6.1** (cf. Proposition 3 of Green et al. (2021)). Under the assumptions (A1) and (A2), with probability greater than $1 - C n \epsilon^{-C n \theta^2 \tilde{\delta}^d}$, there exists a probability measure $\tilde{G}_n$ with density $\tilde{g}_n$ such that
\[ d_\infty(G_n, \tilde{G}_n) \leq C \tilde{\delta}, \]
and such that
\[ \|g - \tilde{g}_n\|_{\infty} \leq C (\theta + \tilde{\delta}), \]
where $C > 0$ is some constant not depending on $n$. 
6.2.2 Discretization And Interpolation Maps

The key procedure adopted in Calder and Trillos (2022) is to construct two maps: a discretization map \( \tilde{P} : L^2(G) \rightarrow L^2(\tilde{G}_n) \) and an interpolation map \( \tilde{I} : L^2(\tilde{G}_n) \rightarrow L^2(G) \), that are "almost" isometries.

For \( X_i, i = 1, \ldots, n \), define \( \tilde{U}_i := \tilde{T}^{-1}(\{X_i\}) \).

Then, we define the contractive discretization map \( \tilde{P} : L^2(G) \rightarrow L^2(\tilde{G}_n) \) by

\[
(\tilde{P}f)(X_i) := n \cdot \int_{\tilde{U}_i} f(x)\tilde{g}_n(x)dx.
\]

Moreover, the interpolation map \( \tilde{I} : L^2(\tilde{G}_n) \rightarrow L^2(G) \) is given by

\[
\tilde{I}u := \Lambda_{\epsilon - 2\delta}(\tilde{P}^*u).
\]

Here, \( \tilde{P}^* = u \circ \tilde{T} \) is the adjoint of \( \tilde{P}_n \), i.e.,

\[
(\tilde{P}^*u)(x) = \sum_{j=1}^{n} u(x_i)1_{x \in U_i},
\]

and \( \Lambda_{\epsilon - 2\delta} \) is a kernel smoothing operator with respect to a kernel \( K \) (defined below) with the bandwidth \( \epsilon - 2\delta \).

The kernel \( K \) is defined by

\[
K(x, y) := \frac{1}{\epsilon^d} \zeta \left( \frac{\|x - y\|}{\epsilon} \right),
\]

where

\[
\zeta(t) := \frac{1}{\sigma_1} \int_0^\infty \eta(s)ds.
\]

Then, define the operator \( \Lambda_h \), for \( h > 0 \), by

\[
\Lambda_h f(x) := \frac{1}{\tau(x)} \int_{X} K(x, y)f(y)g(y)dy,
\]

where \( \tau(x) := \int_{X} K(x, y)g(y)dy \) is a normalization factor.

Furthermore, we define the Dirichlet energies:

\[
b_{w,\epsilon}(u) := \langle L_{w,\epsilon} u, u \rangle g^p - r,
\]

and

\[
D_{w}(f) := \begin{cases} 
\int_X \|\nabla f(x)\|^2 g(x)^{q} dx & \text{if } f \in H^1(X, g), \\
\infty & \text{o.w.}
\end{cases}
\]

Clearly, when \( w = (p, q, r) = (1, 2, 0) \), the above Dirichlet energies become the ones associated with the unnormalized Laplacian, i.e., \( w = (p, q, r) = (1, 2, 0) \):

\[
b_{\epsilon}(u) := \langle (\tilde{D} - \tilde{W})u, u \rangle,
\]

and

\[
D_{2}(f) := \begin{cases} 
\int_X \|\nabla f(x)\|^2 g(x)^{2} dx & \text{if } f \in H^1(X), \\
\infty & \text{o.w.}
\end{cases}
\]

The following two propositions from Green et al. (2021), whose proof is based on Proposition 6.1, shows the fact that discretization map \( \tilde{P} \) and interpolation map \( \tilde{I} \) are almost isometries.
Proposition 6.2 (cf. Proposition 4 of Green et al. (2021)). With probability at least $1 - C n e^{-C n \theta^2 \tilde{d}^d}$, we have for any $f \in L^2(\mathcal{X})$,

$$b_c(\tilde{P}f) \leq C(1 + C(\theta + \tilde{\delta})) \left( 1 + C \frac{\delta}{\epsilon} \right) \sigma_1 \cdot D_2(f),$$

and for any $u \in L^2(G_n)$,

$$\sigma_1 D_2(\tilde{I}u) \leq C(1 + C(\theta + \tilde{\delta})) \left( 1 + C \frac{\delta}{\epsilon} \right) \cdot b_c(u).$$

Proposition 6.3 (cf. Proposition 5 of Green et al. (2021)). With probability at least $1 - C n e^{-C n \theta^2 \tilde{d}^d}$, we have for any $f \in L^2(\mathcal{X})$,

$$\left\| f \right\|^2_{L^2(G)} - \left\| \tilde{P}f \right\|^2_{L^2(G_n)} \leq C \delta \left\| f \right\|_{L^2(G)} \sqrt{D_2(\tilde{f}) + C(\theta + \tilde{\delta}) \left\| f \right\|^2_{L^2(G)}},$$

and for any $u \in L^2(G_n)$,

$$\left\| u \right\|^2_{L^2(G_n)} - \left\| \tilde{I}u \right\|^2_{L^2(G_n)} \leq C \epsilon \left\| u \right\|_{L^2(G_n)} \sqrt{b_c(u) + C(\theta + \tilde{\delta}) \left\| u \right\|^2_{L^2(G_n)}}.$$

Now, as we consider the Dirichlet energies $b_{w,\epsilon}(u)$ and $D_w(f)$ for the weighted Laplacian. Note that by the boundedness assumption of the density $g$, we have there exist constants $C > 0$ and $C' > 0$ such that

$$C' \int_{\mathcal{X}} \| \nabla f_g(x) \|^2 g(x)^q dx \leq \int_{\mathcal{X}} \| \nabla f_g(x) \|^2 g(x)^2 dx \leq C \int_{\mathcal{X}} \| \nabla f_g(x) \|^2 g(x)^q dx.$$

Also, with transformation $v := D^{-r/(q-1)} u$ for $q \neq 1$, we have

$$\langle L_{w,n,\epsilon} u, u \rangle_{g^{p-r}} = \langle (D - W)v, v \rangle.$$

This also holds for $q = 1$ by definition (3). According to Section 6.1, we obtain that there exist constants $C > 0$ and $C' > 0$ such that for large $n$, almost surely,

$$C' b_{w,\epsilon}(u) \leq b_c(u) \leq C b_{w,\epsilon}(u).$$

Consequently, following the proof in Green et al. (2021), we present the following propositions parallelling Proposition 6.2 and 6.3 associated with the weighted case.

Proposition 6.4. With probability at least $1 - C n e^{-C n \theta^2 \tilde{d}^d}$, we have for any $f \in L^2(\mathcal{X}, g^{p-r})$,

$$b_c(\tilde{P}f) \leq C(1 + C(\theta + \tilde{\delta})) \left( 1 + C \frac{\delta}{\epsilon} \right) \sigma_1 \cdot D_2(f),$$

and for any $u \in L^2(G_n)$,

$$\sigma_1 D_2(\tilde{I}u) \leq C(1 + C(\theta + \tilde{\delta})) \left( 1 + C \frac{\delta}{\epsilon} \right) \cdot b_c(u),$$

where $C > 0$ is some constant not depending on $n$ or $f$.

Proposition 6.5. With probability at least $1 - C n e^{-C n \theta^2 \tilde{d}^d}$, we have for any $f \in L^2(\mathcal{X}, g^{p-r})$,

$$\left\| f \right\|^2_{L^2(\mathcal{X}, g^{p-r})} - \left\| \tilde{P}f \right\|^2_{w,n} \leq C \delta \left\| f \right\|_{L^2(\mathcal{X}, g^{p-r})} \sqrt{D_w(\tilde{f}) + C(\theta + \tilde{\delta}) \left\| f \right\|^2_{L^2(\mathcal{X}, g^{p-r})} + \Delta(n, \epsilon, \eta, g) + \epsilon,$$
and for any \( u \in L^2(G_n) \),

\[
\left| \| u \|_{w,n}^2 - \| \tilde{I} u \|_{L^2(X,g^{(p-r)})}^2 \right| \leq C \epsilon \| u \|_{w,n} \sqrt{b_{w,c}(u) + C(\theta + \delta)} \| u \|_{w,n}^2 + \Delta(n, \epsilon, \eta, g) + \epsilon,
\]

where \( C > 0 \) is some constant not depending on \( n \) or \( f \) and

\[
\Delta(n, \epsilon, \eta, g) = \frac{1}{n} \eta_{\text{max}} + \frac{\eta(0)}{ne^d} + \frac{n - 1}{n} \Delta(n, \epsilon),
\]

\[
\Delta(n, \epsilon) := \sqrt{\frac{\log \epsilon}{ne^d}} + \epsilon.
\]

Also, we state the following Weyl’s law whose proof follows Dunlop et al. (2020, Lemma 7.10).

**Proposition 6.6 (Weyl’s law).** There exist constants \( C, C' > 0 \) such that

\[
C' l^{2/d} \leq \lambda_l(L_w) \leq C' l^{2/d},
\]

for all \( l \geq 2 \).

Therefore, by following Green et al. (2021, Proof of Lemma 2) except that we replace Propositions 6.2 and 6.3 by Propositions 6.4 and 6.5, we obtain the following bound for the eigenvalues.

**Lemma 6.1.** Under the assumptions \((A1) \) and \((A2) \), there exist constant \( C, C' > 0 \) and \( N > 0 \) such that for \( n \geq N \) and \( C(\log n/n)^{1/d} \leq \epsilon \leq C \), with probability larger than \( 1 - C n e^{-C n e^d} \), it holds that

\[
C' \min\{l^{2/d}, \epsilon^{-2}\} \leq \lambda_l(L_{w,n,\epsilon}) \leq C \min\{l^{2/d}, \epsilon^{-2}\},
\]

for all \( 2 \leq l \leq n \).
